

Senegal

Mark Horridge

Senegal, on the western tip of Africa, is economically in the middle rank of African countries. Important industries include fishing, fish processing, peanuts and phosphate mining. Energy sources are biomass (firewood) and imported oil. There is (in 2001) no coal or oil production. Subsidized rice from the USA has replaced millet as the staple food. Extensive port facilities at Dakar, the capital, serve Senegal and neighbouring countries such as Mali. The population is about 11 million.

The data source was a 1996 SAM prepared by Dr Mamadou Dansokho and Amadou Diouf in 1999 for the Senegal government. The SAM was supplied by Patrick Osakwe, of the Trade and Regional Integration Division, UN Economic Commission for Africa (UNECA). Conversion of I-O data to GTAP format was performed by Mark Horridge and funded by UNECA through the African Trade Policy Centre.

Some features of the SAM are:

- 33 sectors (see Table 1, Col xxx) with a diagonal MAKE.
- 15 household types
- Commodity flows are measured in purchasers' values (reconciled to producers' values via a vector of margins produced by a Commerce sector) and include both domestic and imported use.
- an accumulation column included investment and inventory use, perhaps errors as well
- an imports vector
- a single vector of sectoral taxes
- remarkably large "own-use" entries; eg, use of paper by paper industry
- documentation in French

The GTAP format requires separate full matrices of basic and tax components for each of domestic and imported goods. To produce these from the SAM we:

- reduced most "own-use" by a factor of 5.
- prorated the margins vector over users and reallocated them to direct use.
- for the accumulation column, treated positive flows of non-agricultural goods as investment use; the remainder as inventory changes.
- prorated the tax vector over users to produce separate basic and tax matrices. We assumed that exports and inventories paid no tax, and that household usage was taxed more heavily.
- prorated the imports vector over non-export users to produce separate imported and domestic basic use matrices. The tax matrix was split using the basic imp/dom shares, and assuming imported goods were taxed more heavily than domestic.
- aggregated sectoral detail which exceeded GTAP's 57 good system.
- added an infinitesimally small coal sector (neither produced nor used in Senegal).

- split Mining sector into OilGas and OtherMining, by assuming that nearly all mining imports were OilGas, and that these were used by the Refining sector.
- uniformly scaled the original values measured in milliard francs CFA to conform with the 2001 US\$ GDP estimate used by Purdue.

The result was a 30-sector I-O table of the format required by Purdue. Table 1 shows the mapping from these 30 sectors to the 33 original sectors and to the 57 GTAP sectors.

Table 1. Mapping between SAM and GTAP sectors
