Abstract: The study assesses the impacts of a formula-based tariff reduction of non-agricultural goods on Brazilian economy, using a multi-region and multi-sector computable general equilibrium (CGE) model. We used a Swiss Formula tariff cut, considering three different coefficients. The CGE model used in the simulation was the *Global Trade Analysis Project* (GTAP) and all tariff shocks were calculated from MACMap database. Besides analyzing macroeconomic and sector results, we have tested the sensibility of the result regarding Armington elasticities increase and the implementation of a simplified agricultural tariff liberalization.

Key words: International trade, Computable General Equilibrium, World Trade Organization, Doha Round, non-agricultural market access.

Impact of the proposals for tariff reductions on non-agricultural goods (NAMA)⁶

Abstract: The study assesses the impacts of a formula-based tariff reduction of non-agricultural goods on Brazilian economy, using a multi-region and multi-sector computable general equilibrium (CGE) model. We used a Swiss Formula tariff cut, considering three different coefficients. The CGE model used in the simulation was the *Global Trade Analysis Project* (GTAP) and all tariff shocks were calculated from MACMap database. Besides analyzing macroeconomic and sector results, we have tested the sensibility of the result regarding Armington elasticities increase and the implementation of a simplified agricultural tariff liberalization.

Key words: International trade, Computable General Equilibrium, World Trade Organization, Doha Round, non-agricultural market access.

1. Introduction: Doha Round and NAMA negotiations

The World Trade Organization Uruguay Round can be said to have determined the elements that would comprise the Doha Round (2001-...), which was introduced as the Development Round, following the awareness that economic results promised by trade liberalization had not matched the expectations of most member nations, i.e., non-developed countries. Trade liberalization remained the key objective of the Round; yet the development issue and the situation of the developing countries (DCs) and of the least developed countries (LDCs) have become an essential element in the discussions, since member countries now admit that tariff reductions are necessary, but not enough to foster a trade liberalization process⁷ and reduce the existing asymmetry between the nations.⁸

Regarding trade negotiations on market access for manufactured or industrial goods, also called Non-Agricultural Market Access (NAMA), the Doha Mandate, in its paragraph 16, sets forth its main objectives: (i) reduction or elimination of tariffs, including: high tariffs, tariff peaks and tariff escalations; (ii) reduction or elimination of non-tariff barriers (NTBs) mainly those applicable to goods of interest to DCs; (iii) tariff consolidation (coverage of all tariff lines). Moreover, trade negotiation asymmetry is admitted, i.e., the specific needs and interests of DCs and LDCs must be considered using the principle of “less than full reciprocity”.⁹

⁶ This study was made possible thanks to support from GVPesquisa. The opinions of the authors do not reflect necessarily the opinion of the institution.

⁷ Proof of this fact is that negotiations of non-tariff barriers and rules are considered essential elements in actual trade liberalization.

⁸ The least developed countries (LDCs) are the focus of special attention.

⁹ Article XXVIII of GATT 1994 and §50 of the Doha Mandate.

In July 2004, following the collapse of the V Cancun Ministerial Conference, WTO members announced the basic structure¹⁰ of the Doha Round negotiations (named Framework/04), to resume, guide and organize the negotiations. In this document, the issue pertaining to NAMA negotiations is covered in its Annex B. The Framework/04 reiterates the positions of Doha Mandate's §16, regarding negotiation of non-agricultural goods. One could say that considerable attention is given to developing a non-linear formula to reduce tariffs applied line by line. According to this document, the formula's main objective would be to reduce or eliminate tariffs and, *a priori*, would not exclude any line.¹¹

According to Framework/04, non-bound tariffs would have to be reduced [2] times the tariff of the most favored nation (MFN) applied, using base year 2001.¹² Moreover, negotiators would have to make a special effort to convert non ad valorem tariffs into equivalent ad valorem tariffs, using a methodology to be defined. Regarding the nomenclature, the document proposes that negotiations initially use the nomenclature of the 1996 Harmonized System (1996HS) or the 2002 Harmonized System (2002HS) but the final result would be based on the 2002HS. Additionally, it reiterates the Mandate's position on environmental non-agricultural goods, sets forth guidelines for negotiating sectorial initiatives,¹³ and points towards elimination of low duties by DCs and other nations. The document also acknowledges the DCs' efforts towards unilateral tariff reduction.

In December 2005, the WTO launched a new document¹⁴ in which, once again, it reiterated the commitments adopted by the Doha Mandate. Regarding the NAMA negotiations, the document incorporated the work of the Negotiating Group on Market Access (NGMA),¹⁵ which can be summed up in the following themes: formulas for tariff reduction, consolidation of tariffs and flexibility for least developed countries.

Regarding the formula for tariff reduction, the document pointed out that members favored the Swiss formula and that discussions were centered on the number and the amounts of the coefficients to be agreed. There were basically two positions: (i) the adoption of a limited number [2] of coefficients: for developed countries this coefficient would be between 5 and 10; for the other countries, between 15 and 30; and (ii) the use of multiple coefficients, according to the average of the bound tariffs for each member.

¹⁰ Doha Work Programme: Decision Adopted by the General Council on 1 August 2004 (WT/L/579) known as the framework of the Doha Round negotiations.

¹¹ To comply with the principle of "less than full reciprocity", Annex B of the Framework/04 received the §8, which deals with possible flexibilities in implementing tariff reductions for DCs and LDCs.

¹² For calculation purposes, import data for the period 1999-2001.

¹³ Sectorial initiatives include discussion of both non-tariff barriers as well as tariffs. There is the need to establish a minimum number of participants per sector before discussions start for a given sector. This is called critical mass. Sectorial initiatives are the following: Automotive, Bicycle and Parts, Footwear, Electric and Electronic, Sports Equipment, Medical and Pharmaceutical Equipment, Precious Stones and Jewelry, Raw Materials, Fishing and Fishing Equipment, Wood Products, IT Products, Forest Products, and Chemical. Brazil's position is not to take part in sectorial initiatives.

¹⁴ Doha Work Programme – Preparations for the Sixth Session of the Ministerial Conference. Available at http://www.wto.org/english/thewto_e/minist_e/min05_e/draft_text2_e.htm

¹⁵ Negotiating Group on Market Access – Progress Report by the Chairman, Ambassador S. H. Jóhannesson, to the Trade Negotiations Committee (TN/MA/16 of 24/Nov/2005).

According to the document, the decision regarding the number and the amounts of the coefficients to be applied depended on the interpretation of the meaning of the principle “less than full reciprocity” for DCs and LDCs.

In addition, it was admitted that the NAMA negotiation would not be included in the Hong Kong Ministerial Conference. Yet some points had to advance to enable the Doha Round to be concluded at the end of 2006, namely: (i) definition of a non-linear formula to be adopted, as well as the number of coefficients and amounts to be applied; (ii) improvement in the understanding regarding the flexibilities to be permitted to DCs and LDCs; and (iii) progress in the discussion on the treatment to be given to non-bound tariffs.

The WTO’s VI Ministerial Conference, held in Hong Kong in December 2005, saw very little progress in relation to the NAMA negotiations, mainly because of the priority given to the agricultural issue. The concluding text of the Hong Kong Conference, in regard to NAMA, mentions the agreement of various member nations on the importance of adopting the Swiss Formula to reduce tariffs, of sectorial initiatives and of tariff consolidation.

In brief, the final statement of the Hong Kong Conference for NAMA pointed out the willingness of member nations to meet the goal of reducing or eliminating high tariffs, tariff peaks and tariff escalations. This should be achieved using the Swiss Formula. The document emphasized that the formula’s structure and details would be agreed simultaneously with the negotiations on agricultural goods market access. Consequently, the success of the NAMA negotiations will depend on progress made by agricultural negotiations, and vice-versa.

2. Objective of the study

The objective of this study is to assess, using a multi-sector and multi-regional computable general equilibrium model, the impact on the Brazilian economy of a tariff reduction on non-agricultural goods. The formula used for the tariff reduction was the Swiss Formula, which associated the final tariff to the initial tariff in a non-linear manner, as shown in the expression $T_f = (B \cdot T_i) / (B + T_i)$, in which T_f is the Final Tariff; B is the Coefficient to be negotiated and T_i = Initial Tariff.

Computable general equilibrium models are widely used to estimate the impact of tariff liberalization on an economy. Recent studies that use computable general equilibrium models for this purpose include those carried out at the Centre d’Études Prospectives et D’Informations Internationales (CEPII), such as Jean, Laborde and Martin (2005) and Bhir, Fontagné and Jean (2005), which were published in Anderson and Martin (2006); regarding studies on Brazil, we can name Ferreira Filho and Horridge (2005), published in Hertel and Winters (2006).

We considered simulations using three coefficients, namely, $B = 15$, $B = 30$, and a combination of $B = 20$ for developing countries and $B = 10$ for least developed countries (hereinafter $B = 20-10$).

The non-linear tariff reduction causes a sharper decrease of the highest tariffs, such as “tariff peaks” and “tariff escalation”, resulting in a more balanced tariff structure. The chart in Figure 1 shows the non-linearity of the Swiss Formula: the higher the initial tariff, the higher the reduction – in percentage terms – defined by the formula. The chart also helps us visualize the role of the coefficient B: the lower the coefficient B, the higher the impact of the formula; the coefficient also defines the tariff ceiling after the reduction. As the initial tariff approaches infinity, the final tariff converges to the coefficient value.

Figure 1: Swiss Formula, the relation between the initial tariff and the final tariff, B = 15 and B = 30.

Source: Authors' own elaboration

This study brings the results of a set of simulations that are part of a wider research project, the aim of which is the assess, on a quantitative basis, the multiple scenarios resulting from the trade negotiation process defined by the mandate of the WTO's Doha Round.

3. Model, databases and construction of a simulation

The study carried out to assess the impact of a manufactured-products tariff reduction on the Brazilian economy used the computable general equilibrium model (the model of the Global Trade Analysis Project – GTAP) and two databases (GTAP and Market Access Mapping – MAcMap).¹⁶

¹⁶ The GTAP model used corresponds to version 6.2, of September 2003, specified for performing the simulations, as mentioned in Section 2.3 below. Using the GTAP model demanded the model's solution software, the GEMPACK, developed by the Monash University, Australia. The GEMPACK version used was the Source-code Version, release 9.0, of April 2005. The database employed by the general equilibrium model

The sections below present details on the databases employed and on the construction of the simulation, i.e., on the regional and sectorial specifications of the general equilibrium model and on the generation of tariff shocks implemented in it.

3.1 The model and the GTAP database

The GTAP simultaneously considers the sectorial interdependence relations of a whole economic system, including those in the domestic economy as well as those in the foreign economies. The GTAP model is a multi-region, multi-sector model, with perfect competition and constant returns to scale, in which bilateral trade is formulated using the Armington approach. Among the model's original characteristics is the treatment of the families' preferences using non-homothetic functional forms of the constant differences in elasticity (CDE) type, explicit treatment of international trade and of transport margins, and a global banking industry, which intermediates global savings and consumption. A detailed description of the model can be found in Hertel (1997). The version used includes 87 regions and 57 economic sectors in the database.

3.2 Market Access Mapping – MacMap

The consolidated and applied tariffs were obtained or estimated from the data provided by MacMap, a database organized by the International Trade Centre (ITC), which combines the United Nations Conference on Trade and Development (Unctad) and the World Trade Organization (WTO) and the Centre d'Études Prospectives et d'Informations Internationales (CEPII).

Among MAcMap's features are:

- Comprehensive coverage of the Preferential Trade Agreements;
- Estimation of ad-valorem equivalents of specific tariffs and tariff quotas; and
- An original methodology for aggregating tariffs. According to this methodology, importing countries are classified by their income (high, medium or low) and degree of liberalization of the economy (high or low). Next, the tariffs applied by a given importing country are weighted according to the imports of this country's reference group of HS6-level goods originating from a given exporting country.

Both the bound tariffs as well as the applied tariffs were aggregated into two digits of the Harmonized System (HS-2). In some cases, the bound tariffs and applied tariffs aggregated into two digits of the Harmonized System are already available in the MAcMap database. When they were not available (especially in the case of tariffs charged by the European Union), they were estimated based on the arithmetic mean of the information available at six digits of aggregation. However, we must point out that we *cannot* say that the estimation method of the tariffs whose aggregation was not available in the MAcMap

is the GTAP Database 6 (Spring 2005), the most recent version available during this research work, which corresponds to the world economy in 2001.

system, i.e., the arithmetic mean based on the HS6, is consistent with the original method. It is merely an approximation.

3.3 Construction of the simulation

3.3.1. Specification of the model: regional and sectorial aggregation

From the regional perspective, the model was specified to represent the world economy through the following countries or regions: Brazil, Argentina, the United States, the European Union, China and the “Rest of the World” (all other countries). According to data of the Brazilian Ministry of Development, Industry and Trade, the European Union, the United States, Argentina and China, in that order, were Brazil's main trading partners in 2004, and in that year accounted for close to 60% of all Brazilian foreign trade.

Figure 2: Brazilian exports, 2005, according to destination, %.

Source: Authors' own elaboration, based on Brazilian Ministry of Development, Industry and Trade data.

From the sector perspective, the analysis used all 57 sectors of the GTAP 6 database.

3.3.2 Generation of tariff shocks

The simulation consisted in multilateral liberalization of trade in non-agricultural goods, by reducing bilateral tariffs involving the countries and regions represented in the model. Figure 3 and Figure 4 show averages and standard deviations of bound tariffs (Figure 3) and of applied tariffs (Figure 4) used in generating the shocks. In all, we considered 25 lists of bilateral tariffs (six countries or regions times five partners, less the tariffs of the “Rest of the World”).

Figure 3: Average and standard deviation of bound tariffs used in generating the shocks

BOUND TARIFFS			
BRA	31.93% (5.84%)	EU	3.50% (3.03%)
ARG	32.48% (5.25%)	CHI	9.78% (4.66%)
USA	2.91% (2.93%)		

Source: Authors' own elaboration, based on MAcMap data. Numbers in parentheses are standard deviations.

Figure 4: Average and standard deviation of applied bilateral tariffs used in generating the shocks

		AVERAGES AND STANDARD DEVIATION OF TARIFFS APPLIED BY				
		BRASIL	ARGENTINA	USA	EU	CHINA
ON GOODS IMPORTED FROM	BRASIL		0.00% (0.00%)	2.08% (3.52%)	2.19% (3.58%)	9.19% (5.09%)
	ARGENTINA	0.11% (0.9%)		2.08% (3.53%)	2.20% (3.59%)	9.19% (5.09%)
	USA	13.06% (6.1%)	12.64% (6.72%)		4.12% (3.84%)	9.19% (5.09%)
	EU	13.06% (6.1%)	12.64% (6.72%)	3.19% (3.53%)		9.19% (5.09%)
	CHINA	13.06% (6.1%)	12.64% (6.72%)	3.29% (3.48%)	2.19% (3.56%)	
	ROW (MFN)	13.06% (6.1%)	12.81% (6.59%)	2.09% (3.54%)	2.19% (3.56%)	9.19% (5.09%)

Source: Authors' own elaboration, based on MAcMap data. Numbers in parentheses are standard deviations.

Based on MAcMap data, we applied the Swiss Formula to the bound tariffs of countries or regions, covering 79 chapters of the Harmonized System, in three different situations:

- Coefficient B = 15, for all countries;
- Combination of coefficients, B = 20 for Argentina, Brazil, China and the “Rest of the World”, and B = 10 for the USA and for the EU – hereinafter “B = 20– 10”;
- Coefficient B = 30, for all countries.

The tariffs obtained in each exercise became the *new upper limits* for the tariffs *currently applied* per country or region to its partners. If the *tariff currently applied* was above the *new bound tariff*, the difference between the two tariffs would “perforate” the new upper limit established. Anytime this occurs, there is the need to reduce the applied tariff, adjusting it to the new limit, which represents a “shock” in the tariff barrier of the

respective sector, the impacts of which were simulated through a computable general equilibrium model.

To identify the Harmonized System (HS) chapters covered by the NAMA negotiation, we decided to exclude the first 24 chapters, which cover most of the farming sector and the so-called agribusiness sector, limiting the NAMA group to the chapters ranging from HS 25 (salt, sulfur, land and stones,...) to 97 (art objects,...)¹⁷.

As an example of this procedure, Figure 5 shows the impact of the application of the Swiss Formula, with the coefficient $B = 15$, on the tariff protection of the Brazilian industrial sectors, classified into two digits according to the Harmonized System. The line with square markers corresponds to the current bound tariffs, per industrial sector; the line with triangles, to the applied tariffs; the line with lozenges, to the bound tariffs after the application of the Swiss Formula with a coefficient of $B = 15$. The vertical bars show the perforations to which some Brazilian industrial sectors would be subject, which correspond to the shocks that will be implemented in the general equilibrium model.

Figure 5: Perforations resulting from the application of the Swiss Formula, with a coefficient of $B = 15$, over bound tariffs for Brazilian industrial goods

Source: Authors' own elaboration, based on MACMap data.

¹⁷ A more detailed list of the HS positions and goods covered by the NAMA negotiations according to the Girard tariff reduction proposal can be found in Forbes et al. (2004, p. A.3)

For example, the bound tariff in chapter 87 of the Harmonized System (which corresponds to the automotive sector) is 34.14%, while the tariff currently applied is 28.78%. After the shock, following the Swiss Formula with a coefficient of $B = 15$, the new bound tariff for this sector would be 10.42%. Therefore, the perforation in the sector's tariff would be 18.36 percentage points (i.e., the difference between 28.78% and 10.42%).

Finally, the chapters of the HS-2 covered in the NAMA negotiations were associated to the available sectors in the GTAP model, as shown in the Annex table.

4. Results of the simulation

The tables and the charts in this section show some selected results of the simulation, of three proposals for tariff reduction, computed according to the Swiss Formula with coefficients of $B = 15$ (Switzerland 15), $B = 30$ (Switzerland 30) and $B = 20-10$ (combination of coefficients, $B = 20$ for developing countries and $B = 10$ for developed countries, Switzerland = 20-10). All results are shown in the form of percentage change from the initial situation.

Figure 6, below, shows a summary of the impacts of the three proposals on the selected macroeconomic variables of the regions included in the simulation.

Figure 6: Summary of the percentage variations of the main macroeconomic variables of the countries and regions included in the simulation, Swiss Formula $B = 15$, $B = 30$ and $B = 20-10$.

Source: Authors' own elaboration.

Among the data pertaining to the Brazilian economy and shown in the above table, we have:

- A modest increase in the real GDP under three scenarios; the greater the liberalization, the higher the rise in the GDP. Although modest, the results suggest that multilateral liberalization of the trade in industrial goods, taken individually, can benefit the Brazilian economy as a whole.
- This result is especially attributable to the sound performance of exports and investments.
- Regarding the trade result, the percentage increase in exports exceeds that of imports in the scenario of smooth liberalization (Swiss 30) and falls short in the scenario of radical liberalization (Swiss 15). In the scenario Swiss 20–10, the percentage increase in exports is close to that of imports.
- Total trade (exports plus imports) would increase more than 5% in the case of coefficient $B = 15$, 2.06% in the case of coefficient $B = 30$, and 3.9% in the third scenario. In comparison, total world trade would increase 0.46% under scenario $B = 15$, and 0.27% under scenario $B = 30$.
- Real consumption of the families, a proxy for well-being, remains practically stable in all scenarios.

Similarly to what happens in Brazil, the impacts on the GDP in all other countries and regions are quite modest, perhaps with the exception of China, where the GDP increases 0.16% in both scenario $B = 15$ as well as scenario $B = 20-10$. The intensity of the impacts on foreign trade is especially noteworthy. Total trade in China increases 6.19% in the more radical scenario, and 4.08% in the smoother scenario. Applying the same intensity criterion, we see a decrease in the income of Argentine families in all three scenarios, at levels similar to those seen in Brazil.

Figure 7, below, shows the percentage impacts on production and employment of the sectors most harmed in the three scenarios.

Figure 7: Brazil, impact on production of the most harmed sectors following the application of the Swiss Formula at coefficients of B = 15, B = 30 and B = 20–10 (%).

Swiss 15	Code	Var% Production	Var% Employment
Motor vehicles and parts	mvh	-5.05	-4.93
Textiles	tex	-1.61	-1.50
Transport equipment nec	otn	-1.28	-1.21
Metal products	fmp	-1.26	-1.22
Chemical, rubber, plastic products	crp	-1.12	-1.01
Manufactures nec	omf	-1.12	-1.04

Swiss 30	Code	Var% Production	Var% Employment

Source: Authors' own elaboration.

Among data found in the table, we have:

- The automotive sector (mvh) is the most harmed in all scenarios, with production falling 5.05% in the scenario of “Swiss 15”, 4.21% in “Swiss 30”, and 4.9% in scenario B = 20–10. In the scenarios of “Swiss 30” and “Swiss 20–10”, in fact, this is the only sector with a negative impact on production above 1% in magnitude.
- In the scenario “Swiss 15”, five sectors other than the automotive have a percentage decrease in production above 1%: Textiles (tex, -1.61%), Transport Equipment (otn, -1.28%), Metal Products (fmp, -1.26%), Chemical, Rubber and Plastic Products (crp, -1.12%) and Other Manufactured (omf, -1.12%).
- From the perspective of employment, the percentage changes are in line with those seen in production.

Production data refer to the percentage change in the amount produced, in physical units of the product. To have a better idea of the impact on actual revenue, we must observe, in addition to the percentage changes of the amounts, the percentage changes in market prices in each sector, as well as the percentage change of the GDP deflator in each

country and region. For instance, market prices in the “mvh” (motor vehicles and parts) sector in Brazil decreased 1.03% under scenario B = 15. Considering production had a percentage reduction of 5.05%, and that the Brazilian GDP had a deflator reduction of 0.9%, we arrive at the percentage reduction in actual revenues of 5.18%. That is, if we consider the *actual revenues* of the “motor vehicles and parts” sector rather than its *production* in physical units, the sector’s situation is further deteriorated. Quite the contrary happens in other sectors. For example, the real revenues of the Metal Products (fmp) sector fell 1.03%, in contrast with a decrease in production of 1.26%.

Figure 8, below, shows the percentage impacts on production and employment of the sectors most benefited in the three scenarios.

Figure 8: Brazil, impact on production of the most benefited sectors following the application of the Swiss Formula at coefficients of B = 15, B = 30 e B = 20-10 (%).¹⁸

¹⁸ The GTAP sector most benefited was “wol” (Wool), under which production increased 1.87% in scenario B = 15, and 1.09% in scenario B = 30. The GTAP “wol” sector would correspond to part of the HS chapters 50 (Silk) and 51 (Wool, Fine or Coarse Animal Hair, etc.), which were translated to the GTAP sector “tex” (Textiles). For this reason, and because this accounts for just a minimal fraction of the Brazilian economy, we preferred to exclude this sector from Figure 15.

We see that:

- In the radical liberalization scenario, six sectors had production increases above 1%: Other Metal Products (nfm, 1.27%); Sea Transport (1.2%); Other Meat Products (omt, 1.18%), Wood Products (lum, 1.15%), Electronic Equipment (1.14%), and Leather Products (1.08%).
- In the smooth liberalization scenario, in spite of changes in the order of the most benefited sectors, none of them had production increases above 1%.
- In the scenario of combined coefficients, the Leather and Footwear (lea, increase of 1.31%), and Other Metal Products (nfm, 1.24%) sectors stand out.
- Similarly to what happens in the previous table, employment percentage changes are in line with production changes.

4.1 Sensitivity analysis

This section analyzes the sensitivity of the macroeconomic results obtained in relation to liberalization parameters and amplitude. For this analysis, the application of the Swiss Formula with a coefficient of $B = 15$ was used as the basic scenario, and its results (such as those shown in Figure 6) were compared to the results obtained in two new situations:

- a. Duplication of the Armington elasticities, which regulate the substitution between demand for domestic and imported supplies, in all countries and regions, including the “Rest of the World”.
- b. Application of an orderly tariff liberalization of agricultural goods (50% reduction in the tariffs shown in the model), at the same time of the tariff shock in industrial goods.¹⁹

The sensitivity of the GTAP results to changes in Armington elasticities is relatively well known and documented (please see Harrison et al, 1997). Specifically, we duplicated the parameter ρ of the function CES, which determines, in the Nested Technology Tree, the substitution between imported and domestic supplies.

The comparison between the macroeconomic results found under the basic scenario (Swiss Formula 15) and those found after duplication of the Armington elasticities are shown in Figure 9.

¹⁹ Agricultural liberalization is considered a sensitivity analysis because in the context of the Doha negotiations the theme covers issues beyond tariff liberalization, such as domestic support and export competition. Please see Section 1.2.3.

An examination of the tables shown in Figure 9 reveals that in comparison to the initial impacts we would have:

- The growth of real GDP increases a significant 33% in Brazil, 50% in Argentina and 81% in China, in spite of less investment in these three nations. For the other countries and regions, the increase in GDP does not appear significant, in spite of a considerable increase in investment in the “Rest of the World”.
- Both imports as well as exports of all countries and regions increased significantly, in line with the duplication of the inputted Armington elasticities. Among the regions, the impact on exports is heterogeneous: relatively elastic in the “Rest of the World” and in Argentina (i.e., the growth in exports more than doubled in response to the duplication of the Armington elasticities); equivalent in Brazil, the European Union and China; and relatively inelastic in the United States (i.e., the growth in exports increased less than proportionally to the Armington elasticities).

- In Brazil and in the United States, a fall in real consumption (and, consequently, in well-being) is intensified, in spite of an increase in the GDP (which, in turn, can be justified by the increase in exports or in government expenditures). In the other countries, real consumption increases, especially in China, or decreases less (as in Argentina).
- In regard to the consumer price index (and also the GDP deflator), we see a sharper price decrease in all countries and regions, except in the European Union and the “Rest of the World”, something which can be explained by an increase in the real consumption witnessed in these two markets.

The comparison between the macroeconomic results obtained under the basic scenario (Swiss Formula 15) and under the scenario that combines the tariff reduction suggested by NAMA and an orderly agricultural liberalization is shown in Figure 10. In this case we imposed a uniform 50% reduction on the agricultural tariffs listed in the database, in all countries and regions of the model, except the “Rest of the World”.

Source: Authors' own elaboration.

We see that:

- The intensity of the real growth of GDP increased for all countries and regions, especially China and the European Union, and except the United States and the “Rest of the World”; in Brazil, we see a combination of an increase in the GDP (50%), significant inflation (from a deflation of 0.9% to an inflation of 0.43%) and a surge in investment (approximately 130%).
- Contrary to what our intuition might suggest, the intensity of the growth in exports *decreased* in Brazil and Argentina, and increased significantly in all other countries and regions, including the European Union. Imports, in turn, increased in all countries. This resulted in a *deterioration* of the trade balance in Brazil and China (in special), and in Argentina (to a smaller degree). In all other countries, we see an *improvement* of the trade balance.
- Real consumption increased in all countries and regions, except in the USA. Consumer prices increased (or decreased less) in Brazil, Argentina and China; in all other countries and regions, consumer prices fell or remained relatively stable (as is the case of the European Union).

Among these results, those relative to foreign trade, especially Brazilian and Argentinean exports and imports, stand out. To get more details on these results, we prepared Figure 11, which shows changes in trade balance (US\$) and in production (%) between the scenarios of “Simultaneous Orderly Agricultural Liberalization” and of “Standard” (B = 15), per good, in millions of US\$, for Brazil.

We see that agricultural liberalization in fact encouraged specialization of the Brazilian production and export of farm and agribusiness products: production and export of goods in these sectors increased, while production and export of industrial products decreased. At the same time, industrial goods produced in Brazil had to compete with similar products produced more efficiently by developed industrial economies, which in the model are represented by the USA and the EU, countries or regions which benefit from the same specialization process, but the other way around.

This process *deteriorated* the Brazilian trade balance deficit, because the rise in the trade balance associated to the farm and agribusiness products was not enough to offset the drop in the trade balance associated to industrial products. In short, the agricultural

liberalization implemented harmed industrial exports, and this loss was not offset by higher agricultural exports.

Figure 11: Brazil, changes in trade balance (US\$) and production (%) between the scenarios of “Simultaneous Orderly Agricultural Liberalization” and of “Standard” (B = 15), main sectors affected, in millions of US\$

Source: Authors' own elaboration.

From the perspective of production, we see the opposite. The increase in the production of farm and agribusiness products would largely offset the decrease in the production of industrial goods, which would justify the rise in the GDP and, consequently, the role of farming and agribusiness in the country's output.

5. Concluding remarks

The computable general equilibrium models are widely used by international organizations – the World Bank, World Trade Organization, United Nations and others – to simulate the expected effects of economic policies, especially in foreign trade. This report presented the results of a study prepared to simulate the isolated effects on the Brazilian economy of the possible results of trade negotiations under the Doha Round, based on a computable general equilibrium model.

Among the possible limitations of the results obtained, in addition to the restrictions raised regarding the method (computable general equilibrium) and the model (GTAP), we must remember that some tariffs, especially those charged by the European Union, have been aggregated in a different manner from that used by the MAcMap database (please see Section 3.2). The regional aggregation used (isolating Brazil's main trading partners, the EU, the USA, Argentina, China, and the “Rest of the World”, in that order) and the translation of the GTAP sectors to the Harmonized System, shown in the Appendix, are the authors' methodological choices; other studies presenting other suggestions of regional aggregation and sectorial translation can arrive at different results.

Among the results, a modest increase in the Brazilian GDP in all three scenarios analyzed stands out. We also identified the sectors which most benefit and most suffer with

such liberalization; chief among them is the automotive sector, the production of which can fall up to 5% in the scenario of greater liberalization.

Additionally, we tested the sensitivity of the results to changes in the Armington elasticities and a simultaneous liberalization of farm tariffs. In the first case, the increase in the GDP was quite sensitive to the increase in the Armington elasticities; in the second case, the agricultural liberalization implemented would harm the exports of the industrial sector, and this loss would not be offset by higher agricultural exports, all of which would result in a deteriorated trade balance.

From the perspective of production, we see the opposite. The increase in the production of farm and agribusiness products would largely offset the decrease in the production of industrial goods, which would justify the rise in the GDP and the role of farming and agribusiness in the country's output. Higher output would result in more investment, which in the end brings further growth, rises in real consumption and greater well-being.

The simulated agricultural liberalization (50% reduction in the agricultural tariffs listed in the GTAP database) is a simplification of the proposals under negotiation in the WTO's Doha Round. A more detailed simulation of the liberalization proposals actually discussed is beyond the scope of this paper and would require additional and deeper studies on this issue.
