Abstract

This paper proposes a framework for gross exports accounting that breaks up a country's gross exports into various value-added components by source and additional double counted terms. By identifying which parts of the official trade data are double counted and the sources of the double counting, it bridges official trade (in gross value terms) and national accounts statistics (in value added terms). Our parsimonious framework integrates all previous measures of vertical specialization and value-added trade in the literature into a unified framework. To illustrate the potential of such a method, we present a number of applications including re-computing revealed comparative advantages and the magnifying impact of multi-stage production on trade costs.

Key Words: Gross export accounting, Global production chains, Trade in value-added.

We thank William Powers for his contributions in the early stage of this research, Peter Dixon and Zhu Kunfu for constructive and generous discussions, the editor (Penny Goldberg) and five referees of this journal and numerous conference and seminar participants for valuable comments, and Nikhil Patel and Joy Glazener for editorial assistance.

1. Introduction

As different stages of production are now regularly performed in different countries, intermediate inputs cross borders multiple times. As a result, traditional trade statistics become increasingly less reliable as a gauge of the value contributed by any particular country. This paper integrates and generalizes the many attempts in the literature at tracing value added by country and measuring vertical specialization in international trade. We provide a unified conceptual framework that is more comprehensive than the current literature. By design, this is an accounting exercise, and does not directly examine the causes and the consequences of global production chains. However, an accurate and well-defined conceptual framework to account for value added by sources is a necessary step toward a better understanding of all these issues.

Supply chains can be described as a system of value-added sources and destinations. Within a supply chain, each producer purchases inputs and then adds value, which is included in the cost of the next stage of production. At each stage, the value-added equals the value paid to the factors of production in the exporting country. However, as all official trade statistics are measured in gross terms, which include both intermediate inputs and final products, they “double count” the value of intermediate goods that cross international borders more than once. Such a conceptual and empirical shortcoming of gross trade statistics, as well as their inconsistency with the System of National Accounts (SNA) accounting standards, has long been recognized by both the economics profession and policy makers.¹

Case studies on global value chains based on detailed micro data for a single product or a single sector in industries such as electronics, apparel, and motor vehicles have provided detailed examples of the discrepancy between gross and value-added trade. While enhancing our intuitive understanding of global production chains in particular industries, they do not offer a comprehensive picture of the gap between value-added and gross trade, and an economy’s participation in cross-border production chains. Several researchers have examined the issue of vertical specialization on a systematic basis, including the pioneering effort of Hummels, Ishii, and Yi (2001) (HIY in subsequent discussion). They suggested that a country can participate in vertical specialization in two ways: (a) uses imported intermediate inputs to produce exports; (b) exports intermediate goods that are used as inputs by other countries to produce goods for export.

¹ See, for example, Leamer et al. (2006), Grossman and Rossi-Hasberg(2008), and Lamy (October 2010).

HIY proposed to measure the imported foreign content in a country's exports based on a country's Input-Output (IO) table.

There are two key assumptions in HIY's foreign content (VS) estimation: the intensity in the use of imported inputs is the same between production for exports and production for domestic sales; and imports are 100% foreign sourced. The first assumption is violated in the presence of processing exports, which is a significant portion of exports for a large number of developing countries (Koopman, Wang and Wei, 2008 and 2012). The second assumption does not hold when there is more than one country exporting intermediate goods.

A growing recent literature aims to estimate value-added trade using global Inter-Country Input-Output (ICIO) tables based on the Global Trade Analysis Project (GTAP) and World Input-Output database (WIOD), such as Daudin, Riffart, and Schweisguth (2011), Johnson and Noguera (2012) and Stehrer, Foster, and de Vries (2012). Most these papers discuss the connections between their works with HIY, but are more closely related to the factor content trade literature, except Koopman et al. (2010). By integrating the literature on vertical specialization and the literature on trade in value added, this paper makes the following contributions:

First, we provide a unified and transparent mathematical framework to completely decompose gross exports into its various components, including exports of value added, domestic value added that returns home, foreign value added, and other additional double counted terms. Measures of vertical specialization and trade in value-added in the existing literature can be derived from this framework and expressed as some linear combinations of these components. We show why some existing measures are special cases of the generalized measures in our framework and why some have to be modified from their original definitions in a more general multi-country framework with unrestricted intermediate trade.

Second, rather than simply excluding double counted items from official trade statistics, we provide an accounting formula that quantifies different types of double counted items for the first time in the literature. Knowing the relative importance of different double counted items in a country's gross exports can help us to gauge the depth and pattern of that country's participation in global production chains. For example, in some sectors, China and the United States may have a similar amount of value added exports. However, the composition of the double counted terms can be very different. For China, the double counted terms may show up primarily in the form of

the use of foreign components (e.g., foreign product designs or machinery) in the final goods that China exports. For the United States, the double counted terms may show up primarily in the form of domestic value added finally returned and consumed at home (e.g., product designs by Apple that is used in the final Apple products produced abroad but sold in the U.S. market). The structure of these double counted items in addition to their total sums offer additional information about the U.S. and China's respective positions in the global value chain.

Third, our accounting framework establishes a precise relationship between value-added measures of trade and official trade statistics, thus providing an observable benchmark for value-added trade estimates, as well as a workable way for national and international statistical agencies to remedy the missing information in current official trade statistics without dramatically changing the existing data collection practices of national customs authorities.

Fourth, our estimated global ICIO table may better capture the international source and use of intermediate goods than in previous databases in two ways. In estimating intermediate goods in bilateral trade, we use end-use classifications (intermediate or final) of detailed import statistics rather than the conventional proportionality assumptions. In addition, we estimate separate input-output coefficients for processing trade in China and Mexico, the two major users of such regimes in the world.

Finally, we report a number of applications to illustrate the potential of our approach to reshape our understanding of global trade. For example, with gross trade data, the business services sector is a revealed comparative advantage sector for India. In contrast, if one uses our estimated domestic value added in exports instead, the same sector becomes a revealed comparative disadvantage sector for India in 2004. The principal reason for this is how the indirect exports of business services are counted in high-income countries. Consider Germany. Most of its manufacturing exports embed German domestic business services. In comparison, most of Indian goods exports use comparatively little Indian business services. Once indirect exports of domestic business services are taken into account, Indian's business service exports become much less impressive relative to Germany and many other developed countries. As another example, the value added decomposition shows that a significant portion of China's trade surplus to the United States in gross trade terms reflects indirect value added exports that China does on behalf of Japan, Korea and Taiwan. While such stories have been understood in qualitative terms, our framework offers a way to quantify these effects.

This paper is organized as follows. Section 2 presents the conceptual framework of gross exports accounting. Section 3 discusses database construction methods, especially on how to estimate the required inter-country IO model from currently available data sources. Section 4 presents a number of illustrative applications. Section 5 concludes.

2. Gross Exports Accounting: Concepts and Measurement

2.1 Concepts

Four measures have been proposed in the existing literature:

1. The first measure of vertical specialization, proposed by HIY (2001), refers to the imported content in a country's exports. This measure, labeled as VS, includes both the directly and indirectly imported input content in exports. In mathematical terms, it can be expressed as:

$$VS = A^M (I - A^D)^{-1} E \quad (1)$$

2. A second measure, also proposed by HIY (2001) and labeled as VS1, looks at vertical specialization from the export side, and measures the value of intermediate exports sent indirectly through third countries to final destinations. However, HIY did not provide a mathematical definition for VS1.

3. A third measure is the value of a country's exported goods that are used as imported inputs by the rest of the world to produce final goods that are shipped back to home. This measure was proposed by Daudin et al (2011). Because it is a subset of VS1, they call it VS1*.

4. A fourth measure is value-added exports, which is value-added produced in source country s and absorbed in destination country r . Johnson and Noguera (2012) defined this measure and proposed to use the ratio of value-added exports to gross exports, or the "VAX ratio" as a summary measure of value-added content of trade.

By definition, as value-added is a "net" concept, double counting is not allowed. As the first three measures of vertical specialization all involve values that show up in more than one country's gross exports, they, by necessity, have to include some double-counted portions of the official trade statistics. This implies that these two types of measures are not equal to each other in general because double counting is only allowed in one of them. They become equal only in some special cases as we will show later both analytically and numerically. In addition, these existing measures are all proposed as stand-alone indicators. No common mathematical

framework proposed in the literature provides a unified accounting for them and spells out their relationships explicitly.

We provide below a unified framework that breaks up a country's gross exports into the sum of various components. The value added exports, VS, VS1, and VS1* are linear combinations of these components. In addition, we show how one may generalize the VS measure without the restrictive assumption made by HIY (no two-way trade in intermediate goods). By properly including various double counted terms, our accounting is complete in the sense that the sum of these well-identified components yields 100% of the gross exports.

For ease of understanding, we start with a discussion of a two-country one sector case in Section 2.2. We relate the components of our decomposition formula with the existing measures in the literature in Section 2.3. We provide several numerical examples in Section 2.4 to show intuitively how our gross exports accounting equation works. Finally, we present the most general G-country N-sector case.

2.2 Two-country case

Assume a two-country (home and foreign) world, in which each country produces in a single tradable sector. The good in that sector can be consumed directly or used as an intermediate input, and each country exports both intermediate and final goods to the other.

All gross output produced by country s must be used as either an intermediate good or a final good, either at home or abroad. So country s ' gross output, x_s , has to satisfy the following accounting relationship:

$$x_s = a_{ss}x_s + a_{sr}x_r + y_{ss} + y_{sr}, r, s = 1, 2 \quad (2)$$

Where y_{sr} is the final demand in country r for the final good produced in Country s , and a_{sr} is the input-output (IO) coefficient, describing units of intermediate goods produced in s used in the production of one unit gross output in Country r . The two-country production and trade system can be written as an inter-country input-output (ICIO) model as follows

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} y_{11} + y_{12} \\ y_{21} + y_{22} \end{bmatrix}, \quad (3)$$

With rearranging, we have

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} I - a_{11} & -a_{12} \\ -a_{21} & I - a_{22} \end{bmatrix}^{-1} \begin{bmatrix} y_{11} + y_{12} \\ y_{21} + y_{22} \end{bmatrix} = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}. \quad (4)$$

Since equation (4) takes into account both the direct and indirect use of a country's gross output as intermediate goods in the production of its own and foreign final goods, the coefficients in the B matrix (Leontief inverse) are referred to as “total requirement coefficients” in the input-output literature. Specifically, b_{11} is the total amount of Country 1's gross output needed to produce an extra unit of the final good in Country 1 (which is for consumption in both Countries 1 and 2); b_{12} is the total amount of Country 1's gross output needed to produce an extra unit of the final good in Country 2 (again for consumption both at home and abroad). Similar interpretations can be assigned to the other two coefficients in the B matrix.

We can break up each country's gross output according to where it is ultimately absorbed by rearranging both countries' final demand into a matrix format by source and destination, and rewrite equation (4) as follows:

$$\begin{bmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{bmatrix} = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \begin{bmatrix} y_{11} & y_{12} \\ y_{21} & y_{22} \end{bmatrix} = \begin{bmatrix} b_{11}y_{11} + b_{12}y_{21} & b_{11}y_{12} + b_{12}y_{22} \\ b_{21}y_{11} + b_{22}y_{21} & b_{21}y_{12} + b_{22}y_{22} \end{bmatrix} \quad (5)$$

where y_{sr} is as defined in equation (2), giving the final goods produced in country s and consumed in country r . This final demand matrix in the middle of equation (5) is a 2 by 2 matrix, summing along each row of the matrix equals y_s , which represents the global use of the final goods produced in each country as specified in equation (4).

We label the 2 by 2 matrix on the left hand side of equation (5) the “gross output decomposition matrix.” It fully decomposes each country's gross outputs according to where it is absorbed. Each element x_{sr} is the gross output in source country s necessary to sustain final demand in destination country r . Summing along its row equals total gross output in country s , x_s as specified in equation (2). For example, it breaks up country 1's gross output x_1 into two parts: $x_1 = x_{11} + x_{12}$. While x_{11} is the part of Country 1's gross output that is ultimately absorbed in country 1, x_{12} is the part of Country 1's gross output that is ultimately absorbed in Country 2.

The RHS of equation (5) further decomposes x_{11} itself into two parts: $x_{11} = b_{11}y_{11} + b_{12}y_{21}$. The first part, $b_{11}y_{11}$ is the part of Country 1's gross output required to produce Country 1's final good that is consumed in Country 1. The second part, $b_{12}y_{21}$, is the part of Country 1's gross output that is exported as an intermediate good, and eventually returns home as part of Country 1's imports from abroad (embedded in foreign final goods).

Similarly, x_{12} can also be decomposed into two parts: $x_{12} = b_{11}y_{12} + b_{12}y_{22}$. The first part, $b_{11}y_{12}$ is the part of Country 1's gross output that is used to produce exported final good that is consumed abroad. $b_{12}y_{22}$ is the part of Country 1's gross output that is exported as an intermediate good and used in country 2 to produce final good that is consumed there. Of course, $x_1 = x_{11} + x_{12}$ is nothing but Country 1's total output. By assumption, they are produced by the same technology and therefore have the same share of domestic value added.

By the same interpretation, Country 2's gross output also can be first broken up into two parts: $x_2 = x_{21} + x_{22}$. x_{21} is Country 2's gross output that is ultimately absorbed in Country 1, which can be in turn broken up to $b_{21}y_{11} + b_{22}y_{21}$. x_{22} is Country 2's domestic absorption of its own gross output, and can be further broken up to $b_{21}y_{12} + b_{22}y_{22}$.

By definition, to produce 1 unit of Country 1's good, a_{11} units of domestic intermediate good is used, and a_{21} units of imported intermediate good is used. Therefore, the fraction of domestic output that represents the domestic value added in Country 1 is $v_1 = 1 - a_{11} - a_{21}$. Similarly, the share of domestic value added in Country 2's gross output is: $v_2 = 1 - a_{12} - a_{22}$. Therefore, we can define a 2×2 direct value-added coefficient matrix as:

$$V = \begin{bmatrix} v_1 & 0 \\ 0 & v_2 \end{bmatrix}. \quad (6)$$

Multiplying V with the Leontief inverse B produces the 2×2 value-added share (VB) matrix, our basic measure of value-added shares by source of production.

$$VB = \begin{bmatrix} v_1 b_{11} & v_1 b_{12} \\ v_2 b_{21} & v_2 b_{22} \end{bmatrix}. \quad (7)$$

Within VB, $v_1 b_{11}$ and $v_2 b_{22}$ denote the domestic value-added share of domestically produced products for country 1 and country 2 respectively; $v_2 b_{21}$ and $v_1 b_{12}$ denote the share of foreign country's value-added in the same goods.² Because all value added must be either domestic or foreign, the sum along each column is unity:

$$v_1 b_{11} + v_2 b_{21} = v_1 b_{12} + v_2 b_{22} = 1. \quad (8)$$

² Note that the VB matrix is not any arbitrary share matrix, but rather the one that reflects the underlying production structure embedded in the ICIO model specified in equations (3). It contains all the needed information on value-added production by source.

Given the assumption on the input-output coefficients, there is no difference in the share of domestic value added in Country 1's production for goods absorbed at home versus its production for exports.³ Therefore, the total domestic value added in Country 1's gross output is simply v_1x_1 ; it is country 1's GDP by definition.

The total value added in Country 1's gross outputs can be easily broken up into two parts based on where it is ultimately absorbed: $v_1x_1 = v_1x_{11} + v_1x_{12}$ where v_1x_{11} is the domestic value added that is ultimately absorbed at home, and v_1x_{12} is the domestic value added that is ultimately absorbed abroad.

The last part, v_1x_{12} , is also Country 1's exports of value added. It is instructive to decompose the last item further. Since $v_1x_{12} = v_1b_{11}y_{12} + v_1b_{12}y_{22}$, Country 1's exports of value added has two components: Country 1's value added embedded in Country 1's exports of final good that is absorbed in Country 2 ($v_1b_{11}y_{12}$); and Country 1's value added in its exports of intermediate good that is used by Country 2 to produce final good that is ultimately locally consumed ($v_1b_{12}y_{22}$).

Note that v_1x_{12} is conceptually the same as Country 1's value added exports as defined by Johnson and Noguera (2012) except that we express it as the sum of two components related only to the final demand in the two countries. To summarize, Country 1's and 2's "value-added exports" are, respectively:

$$\begin{aligned} VT_{12} &\equiv v_1x_{12} = v_1b_{11}y_{12} + v_1b_{12}y_{22} \\ VT_{21} &\equiv v_2x_{21} = v_2b_{21}y_{11} + v_2b_{22}y_{21} \end{aligned} \quad (9)$$

Intuitively, there are at least two reasons for a country's exports of value added to be smaller than its gross exports to the rest of the world. First, the production for its exports may contain foreign value added or imported intermediate goods (a). Second, part of the domestic value added that is exported may return home after being embodied in the imported foreign goods rather than being absorbed abroad (b). In other words, exports of value added are a net concept; it has to exclude from the gross exports both foreign value added and the part of domestic value added that is imported back to home.

³ Such an assumption is maintained by HIY (2001), Johnson and Noguera (2012), and Daudin et al (2011). One might allow part of the production for exports (processing exports) to take on different input-output coefficients. Such a generalization is pursued by Koopman, Wang, and Wei (2012), who have worked out a generalized formula for computing the share of domestic value added in a country's gross exports when processing trade is prevalent.

Identifying and estimating these double counted terms in gross exports have important implications for measuring each country's position in global value-chains. For example, two countries can have identical ratios of value added exports to gross exports but very different ratios of (a) and (b). Those countries that are mainly upstream in global production chains, such as product design, tend to have a large value of (b) but a small value of (a). In comparison, those countries mainly specializing in assembling imported components to produce final products tend to have a small value of (b) but a big value of (a). However, the existing literature lacks a uniform and transparent framework to compute exports of value added, part (a) and part (b) simultaneously. We venture to do this next. Without loss of generality, let us work with country 1's gross exports first:

$$e_{12} = y_{12} + a_{12}x_2 \quad (10)$$

It says that country 1's exports consist of final goods and intermediate goods. Combining (10) with equation (8), we have

$$\begin{aligned} e_{12} &= (v_1b_{11} + v_2b_{21})(y_{12} + a_{12}x_2) = v_1b_{11}y_{12} + v_2b_{21}y_{12} + v_1b_{11}a_{12}x_2 + v_2b_{21}a_{12}x_2 \\ &= v_1b_{11}y_{12} + v_2b_{21}y_{12} + v_1b_{12}y_{22} + v_1b_{12}y_{21} + v_1b_{12}a_{21}x_1 + v_2b_{21}a_{12}x_2 \end{aligned} \quad (11)$$

A step by step proof of $v_1b_{11}a_{12}x_2 = v_1b_{12}y_{22} + v_1b_{12}y_{21} + v_1b_{12}a_{21}x_1$ can be found in appendix A.

Here we give the economic intuition behind it. The total value of country 1's intermediate exports must include two types of value. First, it must include all value added by Country 1 in its imports from Country 2. To see this, we note that in order for exported value produced by Country 1 to come back through its imports, it must have first been embodied in Country 1's intermediate exports, which is $v_1b_{12}y_{21} + v_1b_{12}a_{21}x_1$. Second, it must include all value added generated in Country 1 that is absorbed in Country 2 after being used as intermediate inputs by Country 2, which is $v_1b_{12}y_{22}$.

Note that multiplying the Leontief inverse with intermediate goods exports leads to some double counting of gross output and thus some value terms in exports. However, in order to account for 100% of the value of country 1's intermediate goods exports and to identify what is double counted, we have to include them into the accounting equation first. By decomposing the last two terms further, we can see precisely what is double counted. Using the gross output identity (equation (2)) $x_1 = y_{11} + a_{11}x_1 + e_{12}$ and $x_2 = y_{22} + a_{22}x_2 + e_{21}$, it is easy to show that

$$x_1 = (1 - a_{11})^{-1}y_{11} + (1 - a_{11})^{-1}e_{12} \quad x_2 = (1 - a_{22})^{-1}y_{22} + (1 - a_{22})^{-1}e_{21} \quad (12)$$

$(I - a_{11})^{-1} y_{11}$ is the gross output needed to sustain final goods that are both produced and consumed in country 1, using domestically produced intermediate goods; deducting it from country 1's total gross output, what is left is the gross output needed to sustain country 1's production of its gross exports e_{12} . Therefore the two terms in right hand side of equation (12) both have straightforward economic meanings. We can further show that $b_{12}a_{21}(1 - a_{11})^{-1} y_{11} = b_{11}y_{11} - (1 - a_{11})^{-1} y_{11}$ (see proof, also in Appendix A), which is the total gross output needed to sustain final goods both produced and consumed in country 1, but using intermediate goods that originated in Country 1 and shipped to Country 2 for processing before being re-imported by Country 1 (gross output sold indirectly in the domestic market). These two parts plus $b_{12}y_{21}$ sum to x_{11} in equation (5), which is the gross output of country 1 absorbed in country 1 to sustain its domestic final demand both directly and indirectly. It indicates that Country 1's domestic final demand is satisfied by three production channels: (1) $(I - a_{11})^{-1} y_{11}$ is part of country 1's gross output sold directly in the domestic market that is consumed there; (2) $b_{12}y_{21}$ is part of country 1's gross output used as intermediate goods by country 2 to produce final goods that is consumed in country 1; (3) $b_{12}a_{21}(1 - a_{11})^{-1} y_{11}$ is part of country 1's gross output used as intermediate goods by country 2 to produce intermediate goods that is exported to country 1 to produce final goods in country 1 that is consumed there. They are all needed to sustain the domestic final demand in country 1, but they differ in terms of how they participate in international trade.

Replacing x_1 by $(1 - a_{11})^{-1} y_{11} + (1 - a_{11})^{-1} e_{12}$ and x_2 by $(1 - a_{22})^{-1} y_{22} + (1 - a_{22})^{-1} e_{21}$ in equation (11), and rearranging terms, we can fully decompose Country 1's gross exports into its various value-added and double counted components as follows:

$$\begin{aligned}
 e_{12} &= v_1 b_{11} e_{12} + v_2 b_{21} e_{12} = [v_1 b_{11} y_{12} + v_1 b_{12} y_{22}] \\
 &+ [v_1 b_{12} y_{21} + v_1 b_{12} a_{21} (1 - a_{11})^{-1} y_{11}] + v_1 b_{12} a_{21} (1 - a_{11})^{-1} e_{12} \\
 &+ [v_2 b_{21} y_{12} + v_2 b_{21} a_{12} (1 - a_{22})^{-1} y_{22}] + v_2 b_{21} a_{12} (1 - a_{22})^{-1} e_{21}.
 \end{aligned} \tag{13}$$

While the algebra to arrive at equation (13) may be a bit tedious, expressing a country's gross exports as the sum of these eight terms on the right hand side of equation (13) is very useful. We go over their economic interpretations systematically.

The first two terms in equation (13) (or the two terms in the first square bracket) are value-added exports, i.e. country 1's domestic value-added absorbed outside country 1.

The third term, $v_1 b_{12} y_{21}$ is country 1's domestic value-added that is initially embodied in its intermediate exports but is returned home as part of Country 1's imports of the final good. The fourth term, $v_1 b_{12} a_{21} (1 - a_{11})^{-1} y_{11}$, is also Country 1's domestic value added that is initially exported by Country 1 as part of its intermediate goods to Country 2, but then is returned home via its intermediate imports from country 2 to produce final goods that is absorbed at home. Both the third and the fourth terms are domestic value added produced in Country 1, exported to Country 2, but then return to and stay in Country 1. Both are counted at least twice in trade statistics as they first leave Country 1 for Country 2, and then leave Country 2 for Country 1 (and ultimately stay in Country 1). Note that the value represented by these two terms can be embodied in trade transactions that cross borders back and forth more than twice as long as they originate in Country 1 and are ultimately consumed in Country 1.

The fifth term, $v_1 b_{12} a_{21} (1 - a_{11})^{-1} e_{12}$, may be called a “pure double counted term.” The reason for labeling it as such will become clear after we present a similar dissection of Country 2's gross exports and a further decomposition of this term. This term only occurs when both countries export intermediate goods. If at least one country does not export intermediate goods (i.e., no two-way trade in intermediate goods), this term disappears.

The sixth term, $v_2 b_{21} y_{12}$, is the foreign value-added in country 1's gross exports of final goods; and the seventh term, $v_2 b_{21} a_{12} (1 - a_{22})^{-1} y_{22}$, is the foreign value-added in country 1's gross exports of intermediate goods. They both ultimately go back to the foreign country and consumed there.

The eighth (and the last) term is another pure double counted item in country 1's gross exports. Similar to the 5th term, this term would disappear if at least one country does not export intermediate goods.

In a similar way, we can express Country 2's gross exports as a sum of eight terms:

$$\begin{aligned} e_{21} &= v_1 b_{12} e_{21} + v_2 b_{22} e_{21} = [v_2 b_{21} y_{11} + v_2 b_{22} y_{21}] \\ &+ [v_2 b_{21} y_{12} + v_2 b_{21} a_{12} (1 - a_{22})^{-1} y_{22}] + v_2 b_{21} a_{12} (1 - a_{22})^{-1} e_{21} \\ &+ [v_1 b_{12} y_{21} + v_1 b_{12} a_{21} (1 - a_{11})^{-1} y_{11}] + v_1 b_{12} a_{21} (1 - a_{11})^{-1} e_{12} \end{aligned} \quad (14)$$

Comparing equations (13) and (14), there are a few noteworthy features. First, the 3rd, 4th and 5th terms in Country 1's gross exports (13) are identical to the 6th, 7th, and 8th terms in Country 2's exports (14), and vice versa. This means that, the value added that is initially

produced and exported by Country 1 but then re-imported by Country 1, is exactly the same as foreign value added in Country 2's gross exports to Country 1. Symmetrically, the foreign value added in Country 1's gross exports to Country 2, is the same as Country 2's value added, initially produced and exported by Country 2, but re-appears as part of Country 1's gross exports to Country 2.

Second, while the 1st and 2nd terms in equations (13) and (14) constitute value-added exports, all other terms are double counted components in a country's official exports statistics. However, there are conceptually interesting differences among the 3rd and the 4th terms as the first group, the 6th and the 7th terms as the second group, and the 5th and 8th terms as the third group. The differences are revealed when comparing them to the two countries' GDP. More precisely, a country's GDP is the sum of its value-added exports plus its domestic value-added consumed at home:

$$\begin{aligned} GDP_1 &= v_1 x_1 = v_1 (b_{11}y_{12} + b_{12}y_{22} + b_{12}y_{21} + b_{11}y_{11}) \\ &= v_1 \{b_{11}y_{12} + b_{12}y_{22} + [b_{12}y_{21} + b_{12}a_{21}(1-a_{11})^{-1}y_{11}]\} + v_1(1-a_{11})^{-1}y_{11} \end{aligned} \quad (15)$$

$$\begin{aligned} GDP_2 &= v_2 x_2 = v_2 (b_{21}y_{11} + b_{22}y_{21} + b_{21}y_{12} + b_{22}y_{22}) \\ &= v_2 \{b_{21}y_{11} + b_{22}y_{21} + [b_{21}y_{12} + b_{21}a_{12}(1-a_{22})^{-1}y_{22}]\} + v_2(1-a_{22})^{-1}y_{22} \end{aligned} \quad (16)$$

The last term in each GDP equation is value-added produced and consumed at home that are not related to international trade; while the first four terms in the bracket in each GDP equation are exactly the same as the first four terms in equations (13) and (14). It is easy to show that the sum of global GDP always equals global final demand:

$$\begin{aligned} GDP_1 + GDP_2 &= v_1 x_1 + v_2 x_2 = (1-a_{11}-a_{21})x_1 + (1-a_{12}-a_{22})x_2 \\ &= x_1 - a_{11}x_1 - a_{12}x_2 + x_2 - a_{21}x_1 - a_{22}x_2 = y_1 + y_2 \end{aligned} \quad (17)$$

Equations (15) and (16) show that the 3rd and 4th terms in equations (13) and (14) are counted as part of the home country's GDP (even though they are not part of the home country's exports of value added). Because they represent a country's domestic value-added that is initially exported but imported back and consumed in the initial producing country, they are part of the value-added created by domestic production factors. The 6th and 7th terms represent the foreign value added in a Country's exports that are ultimately absorbed in the foreign country. They are counted once as part of the foreign country's GDP in equations (15) and (16). In comparison, because a combination of the part of GDP that is consumed at home and exports of value added

yields 100% of a country's GDP, the 5th and 8th terms are not part of either country's GDP. In this sense, they are “pure double counted terms.”

Subtracting global GDP from global gross exports using equations (13), (14), (15) and (16) yields the following:

$$e_{12} + e_{21} - GDP_1 - GDP_2 = v_1[b_{12}y_{21} + b_{12}a_{21}(1 - a_{11})^{-1}y_{11}] + v_2[b_{21}y_{12} + b_{21}a_{12}(1 - a_{22})^{-1}y_{22}] \\ + 2v_1b_{12}a_{21}(1 - a_{11})^{-1}e_{12} + 2v_2b_{21}a_{12}(1 - a_{22})^{-1}e_{21} - [v_1(1 - a_{11})^{-1}y_{11} + v_2(1 - a_{22})^{-1}y_{22}] \quad (18)$$

Equation (18) shows clearly that besides the value added produced and consumed at home (in the last square bracket), which is not a part of either country's gross exports, the 6th and 7th terms in equations (13), $v_2[b_{21}y_{12} + b_{21}a_{12}(1 - a_{22})^{-1}y_{22}]$, and the 6th and 7th terms in equation (14) $v_1[b_{12}y_{21} + b_{12}a_{21}(1 - a_{11})^{-1}y_{11}]$, are double counted only once as foreign value-added in the other country's gross exports. Because the 3rd and 4th terms in (13) and (14) reflect part of the countries' GDP, they are not double counted from the global GDP point of view. In comparison, both the 5th and 8th terms are counted twice relative to the global GDP since they are not a part of either country's GDP.

Third, the nature of the 5th and 8th terms can be better understood if we break them up further. In particular, with a bit of algebra, they can be expressed as linear combinations of components of the two countries' final demand:

$$v_1b_{12}a_{21}(1 - a_{11})^{-1}e_{12} = b_{12}a_{21}[v_1b_{11}y_{12} + v_1b_{12}y_{22} + v_1b_{12}y_{21} + v_1b_{12}a_{21}(1 - a_{11})^{-1}y_{11}] \quad (19)$$

$$v_2b_{21}a_{12}(1 - a_{22})^{-1}e_{21} = b_{21}a_{12}[v_2b_{21}y_{11} + v_2b_{22}y_{21} + v_2b_{21}y_{12} + v_2b_{21}a_{12}(1 - a_{22})^{-1}y_{22}] \quad (20)^4$$

The four terms inside the square bracket on the RHS of equation (19) are exactly the same as the first four terms in the gross exports accounting equation (13). A similar statement can be made about the four terms inside the square bracket in equation (20) to gross export accounting equation (14). This means that the 5th and the 8th terms double-count a fraction of both a country's value added exports and its domestic value added that has been initially exported but are eventually returned home. Just to belabor the point, unlike the other terms in Equation (13) that are parts of some countries' GDP, the 5th and the 8th terms over-count the values that are already captured by other terms in gross exports. Again, this feature suggests that they are “pure double counted terms.”

⁴ Proofs of equations (18), (19) and (20) are provided in Appendix A.

Note, if Country 2 does not export any intermediate goods, then $a_{21} = b_{21} = 0$, and the entire RHS of equations (20) and (19) would vanish. Alternatively, if Country 1 does not export intermediate goods, then $a_{12} = b_{12} = 0$, the entire RHS of equations (19) and (20) would also vanish. In other words, the 5th and 8th terms exist only when two-way trade in intermediate goods exist so that some value added is shipped back and forth as a part of intermediate trade between the two countries. Because the eight components of equations (13) and (14) collectively constitute 100% of a country's gross exports, missing any part, including the two pure double counted terms, would yield an incomplete accounting of the gross exports.

Finally, while the 5th and 8th terms in Equation (13) are (double counted) values in intermediate goods trade that are originated in Countries 1 and 2, respectively, we cannot directly see where they are absorbed. By further partitioning the 5th and 8th terms, we can show where they are finally absorbed and interpret the absorption by input/output economics. With a bit of algebra, we can show⁵:

$$\begin{aligned} & v_1 b_{12} a_{21} (1 - a_{11})^{-1} e_{12} + v_2 b_{21} a_{12} (1 - a_{22})^{-1} e_{21} \\ & = a_{12} [b_{21} y_{12} + b_{21} a_{12} (1 - a_{22})^{-1} y_{22}] + a_{21} [b_{12} y_{21} + b_{12} a_{21} (1 - a_{11})^{-1} y_{11}] \end{aligned} \quad (21)$$

Therefore, the sum of 5th and 8th terms in equation (13) is equivalent to the sum of the four terms in the RHS of equation (21). From equation (5), it is easy to see that the terms in the square bracket in equation (21) are parts of x_{22} and x_{11} , *which are trade-related portions of gross output that are both originally produced and finally consumed in the source country*; therefore they are part of each country's gross intermediate exports ($a_{12}x_2$ and $a_{21}x_1$). Since the value added embodied in those intermediate goods are already counted once in the production of each country's GDP (the 3rd and 4th terms in equations (13) and (14)), they are double counted in value-added (GDP) terms. As we pointed earlier, the exact same terms will also appear in Country 2's official exports statistics.

Due to the presence of these types of conceptually different double counting in a country's gross exports, we may separately define “domestic value added in exports” (part of a country's GDP in its exports) and “domestic content in exports.” The former excludes the pure double counted intermediate exports that return home; whereas the latter is the former plus the pure double counted term.

⁵ A step by step proof is in Appendix A.

2.3 Using the accounting equation to generate measures of vertical specialization

We can relate the definitions of the three concepts to components in Equation (13). Country 1's exports of value added are the sum of the 1st and the 2nd term. It takes into account both where the value is created and where it is absorbed. Country 1's *value added in its exports* is the sum of its exports of value added and the 3rd and the 4th terms. This concept takes into account where the value is created but not where it is absorbed. Obviously, Country 1's "value added in its exports" is generally greater than its "exports of value added." Finally, *the domestic content in Country 1's exports* is Country 1's value added in its exports plus the 5th term, the double counted intermediate goods exports that are originated in Country 1. This last concept also disregards where the value is ultimately absorbed. By assigning the 5th term to the domestic content in Country 1's exports, and the 8th term to the foreign content in Country 1's exports, we can achieve the property that the sum of the domestic content and the foreign content yields the total gross exports. We will justify these definitions in what follows.

We already show that the first two terms in Equation (13) correspond to value added exports as proposed in Johnson and Noguera (2012). We now link other measures in the literature to linear combinations of the components in the same gross exports accounting equation. Following HIY's original ideas, Koopman, Wang and Wei (2008 and 2012) have shown that gross exports can be decomposed into domestic content and foreign content/vertical specialization (VS) in a single country IO model without two-way international trade in intermediate goods. If we were to maintain HIY's assumption that Country 1 does not export intermediate good (i.e., $a_{12} = b_{12} = 0$), then the two pure double counted terms, or the 5th and the 8th terms in equation (13) are zero. In this case, we can easily verify that the sum of the last four terms in equation (13) is identical to the VS measure in the HIY (2001) paper.

To remove the restriction that HIY imposed on intermediate trade, we have to determine how to allocate the two pure double counted terms. We choose to allocate the double counted intermediate exports according to where they are originally produced. That is, even though the 5th term in equation (13) reflects pure double counting, it nonetheless is originally produced in Country 1 and therefore can be treated as part of Country 1's domestic content. Similarly, we allocate the 8th term to the foreign content in Country 1's exports. Such a definition is consistent with HIY's original idea that a country's gross exports consist of either domestic or foreign content and the major role of their VS measure is to quantify the extent to which intermediate

goods cross international boarder more than once. It is also computationally simple because the share of domestic and foreign content can be obtained directly from the VB matrix.

However, since the 5th term reflects double counted intermediate goods in a country's gross exports, we may wish to exclude it if we are to consider which part of Country 1's GDP is exported. In particular, we define "domestic value added in Country 1's gross exports" (regardless of where the exports are ultimately absorbed) as the sum of the first four terms on the RHS of equation (13). This variable can be shown to equal to $v_1(1-a_{11})^{-1}e_{12}$, part of equation (12), Country 1's gross output identity.

$$\begin{aligned}
 DV_1 &= v_1(1-a_{11})^{-1}e_{12} = v_1(1-a_{11})^{-1}(y_{12} + a_{12}x_2) \\
 &= v_1(1-a_{11})^{-1}[y_{12} + a_{12}(b_{21}y_{11} + b_{22}y_{21} + b_{21}y_{12} + b_{22}y_{22})] \\
 &= v_1(1-a_{11})^{-1}[(1+a_{12}b_{21})y_{12} + a_{12}(b_{21}y_{11} + b_{22}y_{21} + b_{22}y_{22})] \\
 &= v_1(1-a_{11})^{-1}\{(1-a_{11})b_{11}y_{12} + (1-a_{11})b_{12}(y_{21} + y_{22}) + [(1-a_{11})b_{11} - 1]y_{11}\} \\
 &= v_1b_{11}y_{12} + v_1b_{12}y_{22} + v_1b_{12}y_{21} + v_1[b_{11} - (1-a_{11})^{-1}]y_{11} \\
 &= v_1b_{11}y_{12} + v_1b_{12}y_{22} + v_1[b_{12}y_{21} + b_{12}a_{21}(1-a_{11})^{-1}y_{11}]
 \end{aligned} \tag{22}$$

The derivation uses the property of inverse matrix $(1-a_{11})b_{11} = 1 + a_{12}b_{21}$ and $(1-a_{11})b_{12} = a_{12}b_{22}$.

Following the same frame of thinking, we label only the sum of the 6th and 7th terms, a subset of the foreign content, as the "foreign value added in Country 1's exports," and define country 1's VS as:

$$VS_1 = v_2b_{21}e_{12} = v_2[b_{21}y_{12} + b_{21}a_{12}(1-a_{22})^{-1}y_{22}] + v_2b_{21}a_{12}(1-a_{22})^{-1}e_{21} = (1-v_1b_{11})e_{12} \tag{23}$$

The first two terms are foreign value-added or GDP in country 1's exports, and VS share of country 1 equals v_2b_{21} . Therefore, such a measure of foreign content is a natural extension of HIY's VS measure in a two-country world with unrestricted intermediate goods trade. Because the VS share is defined this way, it is natural to define the domestic content share in country 1's exports as 1- VS share or v_1b_{11} .

In a two-country world, Country 1's VS1 is identical to its VS1* and Country 2's VS:

$$VS1_1 = VS1^*_1 = v_1b_{12}e_{21} = v_1[b_{12}y_{21} + b_{12}a_{21}(1-a_{22})^{-1}y_{11}] + v_1b_{12}a_{21}(1-a_{11})^{-1}e_{12} \tag{24}$$

which is the sum of the 3rd, 4th, and 5th terms in equation (13). However, in a multi-country setting to be discussed later, VS1* will only be a subset of VS1, and the latter will also include some third country terms.

2.4 Numerical examples

To enhance the intuition for our approach, we provide some numerical examples.

Example 1: Two countries, one sector, and only one country exports intermediate good

Consider a world consisting of two countries (USA and CHN) and a single sector of electronics. The two countries have identical gross exports and identical value added exports (and hence identical VAX ratios). The point of this example is to show that the structure of the “double counted” values in gross exports contains useful information.

Both USA and CHN have a gross output of 200. USA’s total output consists of 150 units of intermediate goods (of which, 100 units are used at home and 50 units are exported) and 50 units of final goods (of which 30 are consumed at home and 20 are exported).

CHN’s total output consists of 50 units of intermediate goods (all used at home) and 150 units of final goods (of which, 70 units are exported and 80 units are used at home). By construction, both countries export 70 units of their output (50 units of intermediate goods + 20 units of final goods exported by USA, and 70 units of final goods exported by CHN).

The domestic value added in USA’s output is therefore 100 (=value of gross output 200 – value of domestic intermediate good of 100). Note no foreign value is used in USA’s production. The domestic value added in CHN’s output is also 100 (= value of gross output 200 -value of domestic intermediate goods of 50 – value of imported intermediate goods of 50). The input-output relationship can be summarized as follows:

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 200 \\ 200 \end{bmatrix}, \quad A = \begin{bmatrix} 0.5 & 0.25 \\ 0 & 0.25 \end{bmatrix}, \quad V = \begin{bmatrix} 0.5 & \\ 0 & 0.5 \end{bmatrix}$$

The two-country production and trade system can be written as an inter-country input output (ICIO) model as follows

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0.5 & 0.25 \\ 0 & 0.25 \end{bmatrix} \begin{bmatrix} 200 \\ 200 \end{bmatrix} + \begin{bmatrix} 30 + 20 \\ 70 + 80 \end{bmatrix},$$

The Leontief inverse matrix and the VB matrix can be computed easily as

$$B = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} = \begin{bmatrix} 2 & 0.67 \\ 0 & 1.33 \end{bmatrix}, \quad VB = \begin{bmatrix} 1 & 0.33 \\ 0 & 0.67 \end{bmatrix}$$

We can break up each country’s gross output according to where it is ultimately absorbed by rearrange each country’s final demand as follows:

$$\begin{bmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{bmatrix} = \begin{bmatrix} 2 & 0.67 \\ 0 & 1.33 \end{bmatrix} \begin{bmatrix} 30 & 20 \\ 70 & 80 \end{bmatrix} = \begin{bmatrix} 60 + 46.69 & 40 + 53.3 \\ 0 + 93.33 & 0 + 106.67 \end{bmatrix} = \begin{bmatrix} 106.7 & 93.3 \\ 93.3 & 106.7 \end{bmatrix}$$

It is easy to verify that $x_1 = x_{11} + x_{12}$ and $x_2 = x_{21} + x_{22}$. USA's value-added export is 46.7 ($v_1 x_{12} = 0.5 * 93.33$), where 20 ($= v_1 b_{11} y_{12} = 0.5 * 2 * 20$, first term in equation (13)) is the amount of USA's value added in its export of final goods that is absorbed in CHN, and 26.7 ($= v_1 b_{12} y_{22} = 0.5 * 0.667 * 80$, second term in (13)) is the amount of USA's value added in its export of intermediate goods that is also absorbed in CHN. The amount of USA's value added that is embedded in its export of intermediate goods but returns home as part of CHN's export of final goods is 23.3 ($= v_1 b_{12} y_{21} = 0.5 * 0.667 * 70$, the 3rd term in (13)). Using the terminology of Daudin et al, USA's $VS1^* = 23.3$, the same as the estimates from our accounting equation (13).

By construction, foreign value added in USA's exports equals zero (since CHN does not export intermediate goods by assumption). It is easy to verify that the sum of USA's exports of value added (46.7) and the amount of returned value added (23.3) is 70, which is the value of its gross exports.

For CHN, its value added exports (that are absorbed in USA) are also 46.7 ($= v_2 b_{22} y_{21} = 0.5 * 1.333 * 70$, first term in equation (14)). It is entirely embedded in CHN's exports of final good. However, CHN does import intermediate goods from USA to produce both goods consumed in CHN and goods exported to USA. The amount of USA's value added used in the production of CHN's exports is 23.3 ($= v_1 b_{12} y_{21} = 0.5 * 0.667 * 70$, the 6th term in equation (14)). The sum of CHN's exports of value added (46.7) and the foreign value added in its exports (23.3) is 70, which is the same as CHN's gross exports.

In this example, both countries have identical gross exports and exports of value added, and therefore identical VAX ratios. However, the reasons underlying why value added exports deviate from the gross exports are different. For USA, the VAX ratio is less than one because some of the value added that is initially exported returns home after being used as an intermediate good by CHN in production for exports. For CHN, the VAX ratio is less than one because its production for exports uses intermediate goods from USA which embeds USA's value added.

In addition, the double counted items are also value added at some stage of production. More precisely, the VS in CHN's exports (23.3) is simultaneously a true value added from

USA's viewpoint as it is value added by USA in its exports to CHN (that returned home), but a "double counted item" from CHN's viewpoint as it is not part of CHN's value added.

Since we assume that CHN does not export intermediate goods (or $a_{21}=0$ and $b_{21} = 0$), there is no channel for CHN's gross output to be used by USA in its production and for CHN's gross output to be first exported and then returned home. Therefore, our gross exports accounting equation produces the same estimate for VS as the HIY's formula, i.e:

$$v_2(1-b_{11}) = v_2 b_{21} e_{12} = 0.5 \times 0.667 \times 70 = 23.3 = a_{21}(1-a_{11})^{-1} e_{12} = 0.25 \times (1-0.25)^{-1} \times 70 = 23.3$$

Domestic value-added share for CHN's exports equals $(70-23.3)/70 = 0.667 = v_2 b_{22} = 0.667$. There is no difference between HIY's measure and our method in such a case since there are no pure double counting terms due to two way trade in intermediate goods. Both VS in USA and VS1* in CHN are zero. But this equality will not hold when we remove the assumption of $a_{21}=0$.

However, because there is domestic value-added embodied in USA's intermediate goods exports that is eventually returned home, the domestic value-added share in USA's exports equals to 1. As a result, using the VAX ratio (0.667) as a metric of the share of home country's domestic value-added in its gross exports would produce an underestimate. The corresponding ICIO table and more computation details can be found in online appendix C.

Example 2: Different Sequences of Trade for same final goods consumption and same value-added contribution from each source country

Imagine the US trades in a good that has \$1 million of US value added plus \$100,000 of value added from each of other 5 countries before the final good, priced at \$1.5 million, is consumed in the US. Let us consider two different production sequences of the supply chains.

Case 1: If each of the five countries sends the parts sequentially between them for assembly before they enter the US, then total trade will be \$100K + \$200K + \$300K + \$400K + \$500K = \$1.5 million.

Case 2: If the US exports its part first, then the production proceeds sequentially and the final goods produced by the production chain shipped back to the US, the total trade will be \$1m + \$1.1m + \$1.2m + \$1.3m + \$1.4m + \$1.5m = \$7.5 million.

Both cases yield the same value added but different amounts of gross trade. However, the two sequences of trade will correspond to two different inter-country input-output (ICIO) tables. We can attach concrete labels to the final product and the inputs to get more economic intuition.

Let us think of the final product as a Barbie doll, and the inputs as hair (made by the United States), head, body, hat, clothes, and shoes, respectively. The information about the sequence of the production is embedded in the direct input-output matrix A . In the first case, if the hair is attached by the U.S. at the last stage of production, it is an input to the “doll” industry. While in the second case, if the hair is first exported to the country producing “head,” attached to the “head” there, and re-exported to the next stage of production, it becomes an input to the “head” industry. The two different organizations of the spatial and temporal connections of hair to head show up in changed entries to the ICIO matrix, with inputs of hair to the “doll” industry falling in the former recipient country ICIO coefficient in the first case, but inputs of hair rising in the second country’s “head” industry and measured inputs of heads (now bulked up with the hair value) rising in all head-using industries in all countries downstream from the initial head-producing country to the final “doll” industry that uses heads. While a change in the first country’s hair inputs from the final country’s doll industry to the second country’s head industry in the direct I-O matrix A , the inverse (direct plus indirect request) matrix B will still capture that the hair arrived via the heads. Due to the less direct route of hair to dolls is raising measured inputs in all subsequent stages, as well as in the trade statistics, this case clearly show a rise in gross imports and exports for those downstream of the head industry with only a redirection (not an increase) in exports of hair even though value added is constant by assumption.

In Appendix C, we show how ICIO tables can be constructed for each of the two cases. In each case, our decomposition formula decomposes the gross exports into value added by each source country plus additional double counted terms. The results are reported in Table 1. Because these are very simple examples, we can also decompose the gross exports in each case by economic intuition (see Table 2). The results are identical to what our decomposition formula generates. However, our analytical formula not only clearly shows the structure of a country’s value-added exports (exports in final goods (v_1), in intermediate goods (v_2) and indirect exports via third countries (v_3)), but also further splits the overall double counted amount to what is domestic value-added initially exported and eventually returning home (v_4), what is foreign value-added (v_7), and what is double counted due to intermediate goods imported from foreign countries (v_9). The additional detail provides more information about the structure of both the value-added and the double counted trade. A more detailed two country supply chain example is provided in online appendix D with additional economic intuition.

2.5 The General Case of G Countries and N Sectors

We now discuss the general case with any arbitrary number of countries and sectors. The ICIO model, gross output decomposition matrix, value-added by source shares matrix, are given succinctly by block matrix notations:

$$\begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_G \end{bmatrix} = \begin{bmatrix} I - A_{11} & -A_{12} & \cdots & -A_{1G} \\ -A_{21} & I - A_{22} & \cdots & -A_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ -A_{G1} & -A_{G2} & \cdots & I - A_{GG} \end{bmatrix}^{-1} \begin{bmatrix} \sum_r^G Y_{1r} \\ \sum_r^G Y_{2r} \\ \vdots \\ \sum_r^G Y_{Gr} \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} & \cdots & B_{1G} \\ B_{21} & B_{22} & \cdots & B_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ B_{G1} & B_{G2} & \cdots & B_{GG} \end{bmatrix} \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_G \end{bmatrix} \quad (25)$$

$$\begin{bmatrix} X_{11} & X_{12} & \cdots & X_{1G} \\ X_{21} & X_{22} & \cdots & X_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ X_{G1} & X_{G2} & \cdots & X_{GG} \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} & \cdots & B_{1G} \\ B_{21} & B_{22} & \cdots & B_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ B_{G1} & B_{G2} & \cdots & B_{GG} \end{bmatrix} \begin{bmatrix} Y_{11} & Y_{12} & \cdots & Y_{1G} \\ Y_{21} & Y_{22} & \cdots & Y_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ Y_{G1} & Y_{G2} & \cdots & Y_{GG} \end{bmatrix} \quad (26)$$

$$VB = \begin{bmatrix} V_1 B_{11} & V_1 B_{12} & \cdots & V_1 B_{1G} \\ V_2 B_{21} & V_2 B_{22} & \cdots & V_2 B_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ V_G B_{G1} & V_G B_{G2} & \cdots & V_G B_{GG} \end{bmatrix} \quad (27)$$

With G countries and N sectors, A , and B are $GN \times GN$ matrices; V and VB are $G \times GN$ matrices. V_s denotes a 1 by N row vector of direct value-added coefficient, A_{sr} is a $N \times N$ block input-output coefficient matrix, B_{sr} denotes the $N \times N$ block Leontief inverse matrix, which is the total requirement matrix that gives the amount of gross output in producing country s required for a one-unit increase in final demand in destination country r . X_{sr} is a $N \times 1$ gross output vector that gives gross output produced in s and absorbed in r . $X_s = \sum_r^G X_{sr}$ is also a $N \times 1$ vector that gives country s ' total gross output. Y_{sr} is a $N \times 1$ vector give final goods produced in s and consumed in r . $Y_s = \sum_r^G Y_{sr}$ is also a $N \times 1$ vector that gives the global use of s ' final goods. Both the gross output decomposition and final demand matrix in equation (26) are $GN \times G$ matrices.

Let $\hat{V}_s$ be a N by N diagonal matrix with direct value-added coefficients along the diagonal. (Note $\hat{V}_s$ has a dimension that is different from V_s). We can define a GN by GN diagonal value-added coefficient matrix as

$$\hat{V} = \begin{bmatrix} \hat{V}_1 & 0 & \cdots & 0 \\ 0 & \hat{V}_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \hat{V}_G \end{bmatrix} \quad (28)$$

Using the similar intuition as we used to derive equation (9) in the two country one sector case, we can obtain domestic value-added in a country's gross output by multiplying this value-added coefficient matrix with the right hand side of equation (26), the gross output decomposition matrix. This will result in a GN by G value-added production matrix $\hat{V}BY$ as

$$\hat{V}BY = \begin{bmatrix} \hat{V}_1 & 0 & \cdots & 0 \\ 0 & \hat{V}_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \hat{V}_G \end{bmatrix} \begin{bmatrix} X_{11} & X_{12} & \cdots & X_{1G} \\ X_{21} & X_{22} & \cdots & X_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ X_{G1} & X_{G2} & \cdots & X_{GG} \end{bmatrix} = \begin{bmatrix} V_1 \sum_r^G B_{1r} Y_{r1} & V_1 \sum_r^G B_{1r} Y_{r2} & \cdots & V_1 \sum_r^G B_{1r} Y_{rG} \\ V_2 \sum_r^G B_{2r} Y_{r1} & V_2 \sum_r^G B_{2r} Y_{r2} & \cdots & V_2 \sum_r^G B_{2r} Y_{rG} \\ \vdots & \vdots & \ddots & \vdots \\ V_G \sum_r^G B_{Gr} Y_{r1} & V_G \sum_r^G B_{Gr} Y_{r2} & \cdots & V_G \sum_r^G B_{Gr} Y_{rG} \end{bmatrix} \quad (29)$$

Elements in the diagonal columns give each country's production of value-added absorbed at home. As in the two country case, exports of value-added can be defined as the elements in the off-diagonal columns of this GN by G matrix as

$$VT_{sr} \equiv V_s X_{sr} = V_s \sum_g^G B_{sg} Y_{gr} \quad (30)$$

Obviously, it excludes value-added produced by the home country that returns home after being processed abroad. A country's total value-added exports to the world equal:

$$VT_{s*} = \sum_{r \neq s}^G V_s X_{sr} = V_s \sum_{r \neq s}^G \sum_{g=1}^G B_{sg} Y_{gr} \quad (31)$$

By rewriting equation (31) into three groups according to where and how the value-added exports are absorbed, we obtain decomposition as follows:

$$VT_{s*} = V_s \sum_{r \neq s}^G B_{ss} Y_{sr} + V_s \sum_{r \neq s}^G B_{sr} Y_{rr} + V_s \sum_{r \neq s}^G \sum_{t \neq s, r}^G B_{sr} Y_{rt} \quad (32)^6$$

This is the value-added export decomposition equation in terms of all countries' final demands. The first term is value-added in the country's final goods exports; the second term is value-added in the country's intermediate exports used by the direct importer to produce final goods consumed by the direct importer; and the third term is value-added in the country's intermediate exports used by the direct importing country to produce final goods for third countries. Comparing with equation (9), we can see clearly what is missing in our two country case: it is the re-export of value-added via third countries, the last term of the RHS of equation (32), because the distinction between value-added exports from direct and indirect sources only can be made in a setting with three or more countries.

Define a country's gross exports to the world as:

$$E_{s*} = \sum_{r \neq s}^G E_{sr} = \sum_{r \neq s}^G (A_{sr} X_r + Y_{sr}) \quad (33)$$

Using the logic similar to the derivation of equations (11), we can first decompose a country's gross exports to its various components as follows:

$$\begin{aligned} uE_{s*} &= V_s B_{ss} E_{s*} + \sum_{r \neq s}^G V_r B_{rs} E_{s*} \\ &= VT_{s*} + \{V_s \sum_{r \neq s}^G B_{sr} Y_{rs} + V_s \sum_{r \neq s}^G B_{sr} A_{rs} X_s\} + \{\sum_{t \neq s}^G \sum_{r \neq s}^G V_t B_{ts} Y_{sr} + \sum_{t \neq s}^G \sum_{r \neq s}^G V_t B_{ts} A_{sr} X_r\} \end{aligned} \quad (34)^7$$

Based on the gross output identity for each country $X_s = Y_{ss} + A_{ss} X_s + E_{s*}$, we have,

$$X_s = (I - A_{ss})^{-1} Y_{ss} + (I - A_{ss})^{-1} E_{s*} \quad X_r = (I - A_{rr})^{-1} Y_{rr} + (I - A_{rr})^{-1} E_{r*} \quad (35)$$

Replace X_s and X_r in equation (34), insert equation (32), we obtain the G country, N sector generalized version of gross exports accounting equation as follows:

$$\begin{aligned} uE_{s*} &= \{V_s \sum_{r \neq s}^G B_{ss} Y_{sr} + V_s \sum_{r \neq s}^G B_{sr} Y_{rr} + V_s \sum_{r \neq s}^G \sum_{t \neq s, r}^G B_{sr} Y_{rt}\} \\ &+ \{V_s \sum_{r \neq s}^G B_{sr} Y_{rs} + V_s \sum_{r \neq s}^G B_{sr} A_{rs} (I - A_{ss})^{-1} Y_{ss}\} + V_s \sum_{r \neq s}^G B_{sr} A_{rs} (I - A_{ss})^{-1} E_{s*} \\ &+ \{\sum_{t \neq s}^G \sum_{r \neq s}^G V_t B_{ts} Y_{sr} + \sum_{t \neq s}^G \sum_{r \neq s}^G V_t B_{ts} A_{sr} (I - A_{rr})^{-1} Y_{rr}\} + \sum_{t \neq s}^G V_t B_{ts} A_{sr} \sum_{r \neq s}^G (I - A_{rr})^{-1} E_{r*} \end{aligned} \quad (36)$$

⁶ This value-added exports decomposition could also be done at the bilateral level; however, it is different from equation (15) in Johnson and Noguera (2012), who split bilateral gross exports to three groups.

⁷ The step by step proof is provided in online Appendix B.

Equation (36) has nine terms. It is very similar to equations (13) and (14) in the two country case with only one main difference. It has an additional term, representing indirect value-added exports via third countries, in its value-added exports besides the two value-added terms that directly absorbed by the direct importer. Therefore, the first three terms are value-added exports (only two terms in the two country case). The 4th and 5th term in the second bracketed expression, includes the source country's value-added in both its final and intermediate goods imports, which are first exported but eventually returned and consumed at home, both of which are parts of the source country's GDP but represent a double counted portion in official gross export statistics, and have a similar economic interpretation as the 3rd and 4th terms in equations (13) and (14). They differ from the two country case in that we have to account for the domestic value-added returning home from each of the G-1 countries here, not just from Country 2. The 7th and 8th terms in the third bracketed expression represent foreign value-added (GDP) in the source country's gross exports, including foreign GDP embodied in both final and intermediate goods. They differ from the 6th and 7th terms in equation (13) in the two country case in that equation (36) further partitions each of the foreign value added by individual country sources. There are also two pure double counted terms, the 6th and the 9th terms in equation (36) as equations (13) and (14), but they sum up the double counted portions of two way intermediate trade from all bilateral routes, not just between Country 1 and 2. The complete gross exports accounting made by equations (36) is also diagrammed in Figure 1.

Similar to the two country case, measures of vertical specialization can be expressed as linear combination of the various components identified by equations (36) as follows:

$$DV_s = V_s(I - A_{ss})^{-1}E_{s*} = VT_{s*} + V_s \sum_{r \neq s}^G B_{sr}Y_{rs} + V_s \sum_{r \neq s}^G B_{sr}A_{rs}(I - A_{ss})^{-1}Y_{ss} \geq \sum_r^G VT_{s*} \quad (37)$$

This is the first five terms in equation (36) and clearly shows that a country's domestic value-added in its exports is generally greater than its value-added exports in aggregate. The two measures equal each other only in the case where there is no returned domestic value-added in imports, i.e. when both $V_s \sum_{r \neq s}^G B_{sr}Y_{rs}$ and $\sum_{r \neq s}^G B_{sr}A_{rs}(I - A_{ss})^{-1}Y_{ss}$ are zero.

$$\begin{aligned}
VS_s &= \sum_{t \neq s}^G \sum_{r \neq s}^G V_t B_{ts} Y_{sr} + \sum_{t \neq s}^G \sum_{r \neq s}^G V_t B_{ts} A_{sr} (I - A_{rr})^{-1} Y_{rr} + \sum_{t \neq s}^G V_t B_{ts} A_{sr} \sum_{r \neq s}^G (I - A_{rr})^{-1} E_{r*} \\
&= \sum_{r \neq s}^G V_r B_{rs} E_{s*} = \sum_{t \neq s}^G \sum_{r \neq s}^G V_t B_{ts} Y_{sr} + \sum_{t \neq s}^G \sum_{r \neq s}^G V_t B_{ts} A_{sr} X_r
\end{aligned} \tag{38}$$

which is composed of the last three terms in equation (36).

We can verify that equation (38) is reduced to more familiar expressions in some special cases. Using a single country IO model, Koopman, Wang and Wei (2008, 2012) have shown

$$VS \text{ share} = u - A_v (I - A^D)^{-1} = u A^M (I - A^D)^{-1} \tag{39}$$

In the G-country world,

$$VS \text{ share} = \sum_{r \neq s}^G V_r B_{rs} = u - V_s B_{ss} = u - V_s (I - A_{ss})^{-1} - \sum_{r \neq s}^G V_s B_{sr} A_{rs} (I - A_{ss})^{-1} \tag{40}^8$$

The last term in the last step can be interpreted as the adjustment made for domestic content returned to the source country. Therefore, our foreign content measure of gross exports is a natural generalization of HIY's VS measure in a multi-country setting with unrestricted

intermediate goods trade. Because $\sum_{r \neq s}^G V_r B_{rs} + V_s B_{ss} = u$, it is natural to define a country's

domestic content in its exports as:

$$DC_s = V_s B_{ss} E_{s*} = VT_{s*} + V_s \sum_{r \neq s}^G B_{sr} Y_{rs} + V_s \sum_{r \neq s}^G B_{sr} A_{rs} X_s \geq DV_s \geq \sum_r VT_{sr} \tag{41}$$

This is the sum of the first 6 terms in equation (36).⁹ It shows that a country's domestic content in its exports is generally greater than the part of its GDP in exports therefore is also greater than its value-added exports in the aggregate. The three measures equal each other only in the case

where there is no returned domestic value in imports, i.e. when both $V_s \sum_{r \neq s}^G B_{sr} Y_{rs}$ and

$V_s \sum_{r \neq s}^G B_{sr} A_{rs} X_s$ are zero.

The second HIY measure of vertical specialization (VS1) measures the value of the exported goods that are used as imported inputs by other countries to produce their exports. Although an expression for such indirectly exported products has not been previously defined

⁸ See online appendix B for the step by step proof.

⁹ Note that the third term can be further decomposed into two terms (the 5th and 6th terms) in equation (36).

mathematically in the literature, it can be specified based on some of the terms in our gross exports accounting equations.

$$VS1_s = V_s \sum_{r \neq s}^G B_{sr} E_{r*} = V_s \sum_{r \neq s}^G \sum_{t \neq s, r}^G B_{sr} Y_{rt} + V_s \sum_{r \neq s}^G \sum_{t \neq s, r}^G B_{sr} A_{rt} X_t + V_s \sum_{r \neq s}^G B_{sr} Y_{rs} + V_s \sum_{r \neq s}^G B_{sr} A_{rs} X_s \quad (42)$$

This means HIY's VS1 can be expressed as the third term in (36) plus the third and fifth terms in equation (34). The second term in equation (42) measures how much domestic content in exported goods from the source country is used as imported inputs to produce other countries' intermediate goods exports. It also shows clearly that HIY's VS1 measure is generally greater than indirect value-added exports because the latter only includes the first term of (42), but excludes domestic content that is returned home and the value embodied in intermediate goods exports via third countries (they are already counted as other countries' foreign content in these third countries' exports), i.e.

$$IV_s = V_s \sum_{r \neq s}^G \sum_{t \neq s, r}^G B_{sr} Y_{rt} \leq VS1_s \quad (43)$$

Compared with equation (24) of the definition of VS1 in the two-country case, two additional terms (the first two terms) appear on the RHS of (42) because of the third country effect.

$$VS1_s^* = \sum_{s \neq t} V_s B_{sr} E_{rs} = V_s \sum_{r \neq s}^G B_{sr} Y_{rs} + V_s \sum_{r \neq s}^G B_{sr} A_{rs} X_s \quad (44)$$

As equation (44) shows, we define VS1* as a subset of VS1 similar to Daudin et al. (2011), but our definition differs from theirs as they include only domestic value-added returned home in final goods imports (the first term in equation (44)) but exclude domestic content returned home by being embodied in the imports of intermediate goods, the second term in equation (44).¹⁰ If one omits the second term, then VS1* would be inconsistent with the core idea of measuring vertical specialization from the export side, as it would fail to account for the source country's exports used by third countries to produce their export of intermediate goods. It would therefore consistently under-estimate actual vertical specialization. To put it differently, the same domestic content embodied in a country's intermediate goods exports manifests itself in international trade flows in two ways: (a) as foreign content in other countries exports, and (b) as the source country's indirect exports of domestic content via a third country. In other words, the foreign content in one country's exports is the domestic content of another country embodied in

¹⁰ Note that the second term can be further decomposed into two terms (the 5th and 6th terms) in equation (36).

its indirect exports. As an example, the Japanese content in the form of Japanese-made computer chips used in China's exports of electronic toys to the United States represents foreign content in China's exports, and it is also simultaneously Japan's indirect exports of its domestic content to the United States. While these two perspectives produce the identical numbers when aggregating across all countries at the global level, their values for a given country can be very different. Therefore, when measuring a country's participation in vertical specialization it is useful to be able trace the two perspectives separately. This is also why HIY proposed two measures of vertical specialization, because a complete picture of vertical specialization and a country's position in a vertical integrated production network has to involve both measures. Indeed, for a given country, the ratio of the two measures provides insight for the country's position in global value chains. Downstream countries tend to have a higher share of vertical specialization from the import side, i.e higher foreign content (VS) in their exports, while upstream countries tend to have a higher share of vertical specialization from export side (VS1), higher share of exports via third countries. In addition, as we show in both equations (13) and (36), ignoring domestic content returning home via intermediate goods imports would leave the gross export accounting incomplete.

Therefore, equation (36) provides a new way of thinking about the gross exports statistics. It demonstrates that various double counted items in gross exports can be used to gauge the depth of a country's participation in global production chains. Simply stripping away double counted items and focusing just on value added trade would miss such useful information. We have already provided numerical examples earlier to illustrate the intuition of this point; now we have laid out the accounting equation in a more general multi-country setting. It provides a transparent framework that allows various value-added and double counted components in a country's official gross exports statistics to be correctly identified and estimated.

Equation (36) (or Figure 1) also integrates the older literature on vertical specialization with the newer literature on trade in value added, while ensuring that the sum of value-added components from all sources and the additional double counted intermediate goods exports (due to back-and-forth trade in intermediate goods) yields total gross exports. The previous vertical specialization literature only decomposes gross exports into two components: domestic and foreign content. In comparison, Equation (36) shows that a country's domestic content can be further broken up into sub-components that reveal the destinations for a country's exported value

added, including its own value-added that returns home in its imports and what is double counted due to cross border intermediate goods trade. Similarly, equation (36) also traces out the foreign content in a country's exports to its sources.

Finally, note that we use a single subscript for the domestic content measure and two subscripts for the trade in value-added measure. This is to suggest that the trade in value-added measure holds for both aggregate and bilateral trade, while the gross export accounting equation we propose only holds for a country's total exports to the world.

3. Data and results

3.1 The construction of an Inter-Country Input-output (ICIO) table and its data sources

To implement the above accounting method, we need an inter-country input output (ICIO) table, that is, a database detailing international production and use for all flows of value added. The database should specify (a) transactions of intermediate products and final goods within and between each country at the industry level, (b) the direct value-added in production of each industry in all countries, and (c) the gross output of each industry in all countries. Such an ICIO table goes beyond a collection of single-country IO tables. It specifies the origin and destination of all transaction flows by industry as well as every intermediate and/or final use for all such flows. However, these tables are not available on a global basis, and in fact are rarely available at the regional level. The available global databases, such as the GTAP Multi-Country Input-Output (MCIO) tables, do not have enough detail on the cross-border supply and the use of goods to be directly used to implement our methodological framework.

To provide a workable dataset and empirically conduct gross export decomposition, we construct a global ICIO table for 2004 by integrating the GTAP database (version 7) and the additional information from UN COMTRADE using a quadratic mathematical programming model. The model (a) minimizes the deviation of the resulting new data set from the original GTAP data, (b) ensures that supply and use balance for each sector and every country, and (c) keeps all sectoral bilateral trade flows in the GTAP database constant. The new database covers 26 countries and 41 sectors¹¹.

¹¹ Tsigas, Wang and Gehlhar (2012) provides details on the construction of the database. The longer working paper lists the countries/regions and sectors in our sample and their concordance to the GTAP database.

To estimate these detailed inter-industry and inter-country intermediate flows, we need to (i) separate gross bilateral trade flows at the sector level in the GTAP database into intermediate, consumption and investment goods trade flows, and (ii) allocate intermediate goods from a particular country source to each sector it is used within all destination countries. We address the first task by concording the three end-use categories defined by UN Broad Economic Categories (BEC) to the 6-digit HS level bilateral trade data in COMTRADE. This differs from Johnson and Noguera (2012) and Daudin, Riffart, and Schweisguth (2011), who also transform the MCIO table in the GTAP database into an ICIO table. However, they do not use detailed trade data to identify intermediate goods in each bilateral trade flow, but apply a proportionality method directly to the GTAP trade data; i.e., they assume that the proportion of intermediate to final goods is the same for domestic supply and imported products.

The use of end-use categories to distinguish imports by use is becoming more widespread in the literature and potentially avoids some noted deficiencies in the proportionality method. Feenstra and Jensen (2009) use a similar approach to separate final goods from intermediates in U.S. imports in their recent re-estimation of the Feenstra-Hanson measure of material off-shoring. Dean, Fung, and Wang (2011) show that the proportionality assumption underestimates the share of imported goods used as intermediate inputs in China's processing trade. Nordas (2005) stated that the large industrial countries have a higher share of intermediates in their exports than in their imports, while the opposite is true for large developing countries. These results imply that the intermediate content of imports differs systematically from the intermediate content in domestic supply.

In theory, less distorted intermediate share estimates will provide a better row total control for each block matrix of A_{sr} in the ICIO coefficient matrix A , thus improving the accuracy of the most important parameters (the inter country IO coefficients) in an ICIO model. This is why distinguishing imports by BEC may improve ICIO database quality over the proportionality assumption. To precisely assess whether and how much the BEC method improves over the proportionality approach, one would need the true inter-country IO coefficients as a "reference point", which unfortunately do not exist on a global scale. We will provide some evidence that the two alternative ways to identify intermediate goods from bilateral trade flows in the literature have a significant impact on trade cost when the magnification effects of multi-stage production are taken into account in one of our application examples.

3.2 Complete accounting of gross exports

Table 3 presents a complete accounting of each country's gross exports in 2004 using equation (36). The column numbers correspond to the order of each item in the equations and also the box numbers in Figure 1. The first three columns also correspond to the three terms in the RHS of equation (32).

We compute all these nine terms independently and verify that they sum to exactly 100 percent of gross exports. The resulting estimates constitute the first such decomposition in a global setting and clearly highlight what is double counted in the official trade statistics. Column (15) reports the percentage of double counting by adding columns (4) to (9). At the global level, only domestic value added in exports absorbed abroad are value-added exports. In addition to foreign content in exports, domestic content that returns home from abroad is also a part of double counting in official trade statistics, since it crosses borders at least twice. Such returned value added has to be separated from domestic value-added absorbed abroad in order to fully capture multiple counting in official trade statistics. Therefore, for any country's gross exports, the double counting portion equals the share of gross exports in excess of the value-added exports. We estimate this share to be about 25.6% of total world exports in 2004.

The accounting results reported in table 3 also provide a more detailed breakdown of domestic content in exports than has been previously available in the literature. The variations in the relative size of different components across countries provide a way to gauge the differences in the role that countries play in global production networks. For example, for the United States, the share of foreign value-added in its exports was only 9% (columns 7+8), while its own GDP first exported then finally return home is large at 11.3% (columns 4+5), indicating that most of its exports reflect its own domestic value added. In comparison, for China's and Mexico's processing exports, the share of foreign GDP in their gross exports is 46.5% and 55.8% respectively, with an additional 10.1% and 7.6% of their gross exports coming from intermediate goods produced in foreign countries (column 9), indicating domestic value added accounts for less than half the value of both countries' processing exports. More importantly, about half of the double counting in U.S. exports – reflected as 1-VAX ratio (column 11) in column 15 - comes primarily from its own domestic content returning home via imports (12.4% over 25.4%). In contrast, almost all of the double counting in China's and Mexico's processing exports comes from imported foreign content (56.6% over 56.9% and 63.4 over 63.7 respectively). These

calculations highlight U.S. exporters and Chinese and Mexican processing exporters' respective positions at the head and tail of global production chains.

The structure of double counted terms in each country's gross exports listed in columns (4) through (9) offers additional information on how each country participates in vertical specialization and its relative position in global production chains. For example, for Western EU countries, about 40% of its double counted gross exports come from domestic content returned home (7.4/18.9). In comparison, for most developing countries, the foreign content tends to dominate, with only a very tiny portion of their domestic content returning home. Within foreign content, Maquiladora producers in Mexico, export processing zones in China and Vietnam, tend to have a large portion embodied in their final goods exports (37.6%, 34.1% and 24.4%, respectively), reflecting their position as the assemblers of final goods in global production chains. For developed and newly industrialized economies, the shares in intermediate goods exports and the pure double counted portion due to multiple border crossing intermediate goods trade are much higher. Similarly, upstream natural resource producers such as Australia & New Zealand, Russia, Indonesia and Philippines, have a significant portion of their intermediate exports used by other countries to produce their intermediate goods exports. This is also true for upstream producers of manufacturing intermediates such as Japan.

To reiterate the connection of the nine basic components reported in the Table 3 to measures in the existing literature by numerical estimates, column (11) reports the value-added to gross exports (VAX) ratio proposed by Johnson and Noguera (2012) by adding up columns (1), (2), and (3); column (12) list HIY's VS share by summing column (7) , (8) and (9). Column (14) lists the share of domestic content extensively discussed in the vertical specialization literature by summing columns (1) through (6); Finally, column (16) gives the share of vertical trade by adding columns (12) and (13), which is an indicator of how intensively a country is participating in the global production chain.

Comparing domestic content share estimates (Column 14) and Johnson & Noguera's VAX ratio (Column 11) reported in table 3, we see interesting differences between high-income countries and emerging market economies. For most emerging market economies, the numerical difference of these two measures is quite small. This means that only a tiny part of domestic content returns home for most countries. In comparison, for the United States, Western Europe and Japan, the difference between domestic content share and the value added export share is

more significant. This reflects the fact that advanced economies export relatively more upstream components, and some of the value added embedded in these intermediate goods returns home as part of other countries' exports to the advanced economies. Such differences between high-income countries and emerging market economies would not be apparent if one does not compute the domestic content share and the VAX ratio separately.

4. Broad implications for a better understanding of global trade

The decomposition results have implications for a variety of research and policy questions. In this section, to illustrate the potential importance of the decomposition, we briefly discuss a few applications.

4.1 Revealed Comparative Advantage index based on gross and value-added trade

The concept of revealed comparative advantage (RCA for short), proposed by Balassa (1965), has proven useful in many research and policy applications. In standard applications, it is defined as the share of a sector in a country's total gross exports relative to the world average of the same sector in world exports. When the RCA exceeds one, the country is said to have a revealed comparative advantage in that sector; when the RCA is below one, the country is said to have a revealed comparative disadvantage in that sector. The problem of double counting of certain value added components in the official trade statistics suggests that the traditional computation of RCA could be noisy and misleading. The gross exports accounting exercise we proposed in this paper provides a way to remove the distortion of double counting by focusing on domestic value-added in exports. Because domestic value-added or GDP in a country's exports describes the characteristics of a country's production (total domestic factor content in exports), it does not depend on where the exports is absorbed. For those applications in which a production-based RCA is the right measure, we can use GDP in exports to compute RCA.

We re-compute the RCA index at the country-sector level for all the countries and sectors in our database. Due to space constraints, we select two sectors and compare the country rankings of RCAs using both gross exports and domestic value-added in gross exports. In left panel of Figure 2, we report the two sets of RCA indices for the finished metal products sector in 2004. Using gross exports data, both China and India show a strong revealed comparative advantage (ranked the first and fourth, respectively, among the set of countries in our database,

and with the absolute values of RCA at 1.94 and 1.29, respectively). However, when looking at domestic value added in that sector's exports, both countries ranking in RCA drop precipitously to 7th and 15th place, respectively.¹² In fact, for India, the sector has switched from being labeled as a comparative advantage sector to a comparative disadvantage sector. Unsurprisingly, the ranking for some other countries move up. For example, for the United States, not only does its RCA ranking move up from 10th place under the conventional calculation to the 3rd place under the new calculation, but its finished metal products industry also switches from being labeled as a comparative disadvantage sector to a comparative advantage sector.

Another example is the “real estate and business services” sector (right panel of Figure 2). Using data on gross exports, India exhibits a strong revealed comparative advantage in that sector on the strength of its unusually high share of business services exports in its overall exports. However, once we compute RCA using domestic value-added in exports, the same sector becomes a comparative disadvantage sector for India! One key reason for the change is that business services in advanced countries are often exported indirectly by being embedded in these countries manufacturing exports. Indeed, the RCA rankings for the United States, the European Union and Japan all move up using data on the domestic value-added in exports. Therefore, after taking into account indirect value added exports, the Indian share of the sector in its exports becomes much less impressive (relative to other countries).

These examples illustrate the possibility that our understanding of trade patterns and revealed comparative advantage could be modified substantially once we have the right statistics.

4.2 Magnification of trade costs from multi-stage production

As noted by Yi (2003, 2010), multi-stage production magnifies the effects of trade costs on world trade. There are two separate magnification forces. The first exists because goods that cross national borders multiple times incur tariffs and transportation costs multiple times. The second exists because tariffs are applied to gross imports, even though value added by the direct exporter may be only a fraction of this amount. Different ways of participating in global production chain affects the extent to which different countries are affected by such cost

¹² Sectoral value added here includes value produced by the factors of production employed in the finished metal products sector and then embodied in gross exports of all downstream sectors, rather than the value added employed in upstream sectors that are used to produce finished metal products in the exporting country. This distinction is particularly important in the business services sector, discussed next.

magnification. However, Yi (2003) does not actually measure the magnification of tariffs, though it is important to his simulation exercise.

Our gross export accounting method provides an ideal way to re-examine the magnification issue. In Appendix E, we provide an illustrative calculation of the first order magnification effect of using imported intermediate inputs to produce exports. It represents the magnification effect if tariffs were the only factor that augments the trading costs. For instance, we find that one additional stage of production increases trade costs of Vietnam's merchandise production by 80% of its standard tariff. Generally speaking, the magnification effect is stronger for emerging market economies than for developed economies due to the lower domestic value-added share in most developing countries' manufacturing exports. In the same appendix, we also show that global ICIO databases constructed by the BEC end-use classification versus the proportionality assumption produce different trade cost magnification effects for a number of countries.

4.3 Other applications

The set of examples discussed so far certainly does not exhaust the possible applications. For example, the Federal Reserve Board and the IMF routinely compute effective exchange rates using trade weights that are based on gross exports and imports. A conceptually better measure should weight trading partners based on the relative importance in value added trade rather than in gross trade terms. Our decomposition results make it feasible to do such computations.

As another example, for some research or policy questions, one might need to look at the response of a country's bilateral or multilateral trade to exchange rate changes. Once one recognizes that there is a potential mismatch between trade in value added and trade in gross terms, one would want to take this into account. Our decomposition allows for a correction.

As a further example, because a country's gross exports embed value added from other countries, its bilateral trade balance in value added terms can be very different from that in gross trade terms. By our estimation, because China is the final assembler in a large number of global supply chains, and it uses components from many other countries, especially East Asian countries, its trade surplus with US and Western EU countries measured in value-added term is 41% and 49% less than that measured in gross terms in 2004. In contrast, Japan's trade surplus with the U.S. and Western EU countries are 40% and 31% larger measured in value-added terms,

because Japan exports parts and components to countries throughout Asia that are eventually assembled into final products there and exported to the United States and Western EU countries.

5. Conclusions

We have developed a unified conceptual framework that can fully account for a country's gross exports by its various value-added and double counted components. This new framework incorporates all previous measures of vertical specialization and value-added trade in the literature while adjusting for the back-and-forth trade of intermediates across multiple borders. With a full concordance between value-added and double counted components and official gross trade statistics, it opens the possibility for the System of National Accounts (SNA) to accept the concept of value-added trade without dramatically changing current practice of customs trade data collection. This may in turn provide a feasible way for international statistical agencies to report value-added trade statistics regularly in a relatively low cost fashion.

The creation of a database that encompasses detailed global trade in both gross and value-added terms will allow us to move from a largely descriptive empirical exercise to analysis of the causes and consequences of differences in supply chain participation. We show that conventional analyses involving revealed comparative advantage, bilateral trade balance, trade cost or effective real exchange rates can all benefit from our gross exports accounting results.

Better information at the sector level can improve our estimation. For instance, current end use classifications, such as the UN BEC, need to be extended to dual used products and services trade. In addition, methods also need to be developed to properly distribute imports to domestic users either based on cross country statistical surveys or based on firm level and Customs transaction-level trade data. We leave such sector level applications to future research.

Figure 1 Accounting of gross exports: concepts

Note:

- a. value-added exports by a country equals $(1) + (2) + (3)$.
- b. GDP in exports $(1) + (2) + (3) + (4) + (5)$.
- c. domestic content in a country's exports equals $(1) + (2) + (3) + (4) + (5) + (6)$.
- d. $(7) + (8) + (9)$ is labeled as VS, and $(3) + (4) + (5) + (6)$ is part of VS1 labeled by HIY (2001).
- e. (4) are also labeled as VS1* by Daudin et al (2011).
- f. (4) through (9) involve value added that crosses national borders at least twice, and are the sources of multiple counting in official trade statistics.¹³

¹³ (3) should not be included in double counting, because when this value crosses a border for the second time, it becomes foreign value in the direct importer's exports. For this reason, it is not included as double counting to avoid an over-correction.

Table 3 Accounting of gross exports, 2004

Country/region	Value-added exports				Domestic return home	VA	Pure double counting	Foreign return countries	VA foreign	Pure double counting	Connection with existing measures						
	in Billions of US dollars	in direct final exports	in absorb by direct importers	int. by third countries	in final exports	in int. exports	in int. exports produced in home	in final exports	in int. exports	in int. exports produced abroad	Total	VAX ratio	VS share	VS1 share	DC share	Double count share	Share of Vertical trade

Online Appendices

Appendix A: Derivation details for major equations in the two country, one sector model

Based on the property of inverse matrix, we have:

$$\begin{bmatrix} 1-a_{11} & -a_{12} \\ -a_{21} & 1-a_{22} \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \begin{bmatrix} 1-a_{11} & -a_{12} \\ -a_{21} & 1-a_{22} \end{bmatrix} \quad (\text{A1})$$

Therefore, the following identities hold:

$$(1-a_{11})b_{11}-1=a_{12}b_{21}, b_{11}(1-a_{11})-1=b_{12}a_{21}$$

$$a_{21}b_{11}=(1-a_{22})b_{21}, b_{11}a_{12}=b_{12}(1-a_{22})$$

$$(1-a_{22})b_{21}=a_{21}b_{11}, b_{22}a_{21}=b_{21}(1-a_{11})$$

$$a_{21}b_{12}=(1-a_{22})b_{22}-1, b_{22}(1-a_{22})-1=b_{21}a_{12}$$

Therefore,

$$b_{11}=(1-a_{11})^{-1}+[b_{11}(1-a_{11})-1](1-a_{11})^{-1}=(1-a_{11})^{-1}+b_{12}a_{21}(1-a_{11})^{-1} \quad (\text{A2})$$

Given (A2), we have

$$b_{11}y_{11}-(1-a_{11})^{-1}y_{11}=b_{12}a_{21}(1-a_{11})^{-1}y_{11} \quad (\text{A3})$$

$$b_{22}=(1-a_{22})^{-1}+b_{21}a_{12}(1-a_{22})^{-1}$$

Derivation of equation (11)

Using the relationship between gross output x and final demand y specified in equation (5), we have

$$y_2 = y_{21} + y_{22} = (1-a_{22})x_2 - a_{21}x_1 \quad (\text{A4})$$

Also using $b_{11}a_{12} = b_{12}(1-a_{22})$,

$$\begin{aligned} v_1b_{11}a_{12}x_2 &= v_1b_{12}(1-a_{22})x_2 = v_1b_{12}(y_2 + a_{21}x_1) = v_1b_{12}a_{21}x_1 + v_1b_{12}(y_{21} + y_{22}) \\ &= v_1b_{12}y_{22} + v_1b_{12}y_{21} + v_1b_{12}a_{21}x_1 \end{aligned} \quad (\text{A5})$$

Derivation of equations (19) and (20)

Based on equation (6):

$$x_1 = b_{11}y_{11} + b_{12}y_{21} + b_{11}y_{12} + b_{12}y_{22} \quad (\text{A6})$$

From the gross exports identity, we have:

$$x_1 = (1 - a_{11})^{-1}(e_{12} + y_{11}), \quad (1 - a_{11})^{-1}e_{12} = x_1 - (1 - a_{11})^{-1}y_{11} \quad (A7)$$

Combining (A6) and (A7), we can easily show that

$$\begin{aligned} v_1 b_{12} a_{21} (1 - a_{11})^{-1} e_{12} &= v_1 b_{12} a_{21} [x_1 - (1 - a_{11})^{-1} y_{11}] = \\ v_1 b_{12} a_{21} [b_{11} y_{11} + b_{12} y_{21} + b_{11} y_{12} + b_{12} y_{22} - (1 - a_{11})^{-1} y_{11}] & \\ = v_1 b_{12} a_{21} [b_{11} y_{12} + b_{12} y_{22} + b_{12} y_{21} + b_{12} a_{21} (1 - a_{11})^{-1} y_{11}] & \end{aligned} \quad (A8)$$

which is the first pure double counted term in Country 1's gross exports accounting equation (13) that is expressed as function of both countries' final demand.

Also based on equation (6):

$$x_2 = b_{21} y_{11} + b_{22} y_{21} + b_{21} y_{12} + b_{22} y_{22} \quad (A9)$$

Also from gross exports identity,

$$x_2 = (1 - a_{22})^{-1}(e_{21} + y_{22}), \quad (1 - a_{22})^{-1}e_{21} = x_2 - (1 - a_{22})^{-1}y_{22} \quad (A10)$$

Combining (A9) and (A10), we can show that the second pure double counted term in equation (13) can be expressed as:

$$\begin{aligned} v_2 b_{21} a_{12} (1 - a_{22})^{-1} e_{21} &= v_2 b_{21} a_{12} [x_2 - (1 - a_{22})^{-1} y_{22}] = \\ v_2 b_{21} a_{12} [b_{21} y_{11} + b_{22} y_{21} + b_{21} y_{12} + b_{22} y_{22} - (1 - a_{22})^{-1} y_{22}] & \\ = v_2 b_{21} a_{12} [b_{21} y_{11} + b_{22} y_{21} + b_{21} y_{12} + b_{21} a_{12} (1 - a_{22})^{-1} y_{22}] & \end{aligned} \quad (A11)$$

An alternative way to decompose the two pure double counted terms: Derivation of equation (21):

Based on (A1), (A7) and (A9),

$$\begin{aligned} &v_1 b_{12} a_{21} (1 - a_{11})^{-1} e_{12} + v_2 b_{21} a_{12} (1 - a_{22})^{-1} e_{21} \\ &= (1 - a_{11} - a_{21}) b_{12} a_{21} (1 - a_{11})^{-1} e_{12} + (1 - a_{12} - a_{22}) b_{21} a_{12} (1 - a_{22})^{-1} e_{21} \\ &= [(1 - a_{11}) b_{12} a_{21} - a_{21} b_{12} a_{21}] (1 - a_{11})^{-1} e_{12} + [(1 - a_{12}) b_{21} a_{12} - a_{12} b_{21} a_{12}] (1 - a_{22})^{-1} e_{21} \\ &= [a_{12} b_{22} a_{21} - a_{21} b_{12} a_{21}] (1 - a_{11})^{-1} e_{12} + [a_{21} b_{11} a_{12} - a_{12} b_{21} a_{12}] (1 - a_{22})^{-1} e_{21} \\ &= [a_{12} b_{21} (1 - a_{11}) - a_{21} b_{12} a_{21}] (1 - a_{11})^{-1} e_{12} + [a_{21} b_{12} (1 - a_{22}) - a_{12} b_{21} a_{12}] (1 - a_{22})^{-1} e_{21} \\ &= a_{12} b_{21} e_{12} - a_{21} b_{12} a_{21} (1 - a_{11})^{-1} e_{12} + a_{21} b_{12} e_{21} - a_{12} b_{21} a_{12} (1 - a_{22})^{-1} e_{21} \\ &= a_{12} b_{21} [e_{12} - a_{12} (1 - a_{22})^{-1} e_{21}] + a_{21} b_{12} [e_{21} - a_{21} (1 - a_{11})^{-1} e_{12}] \\ &= a_{12} b_{21} \{y_{12} + a_{12} [x_2 - (1 - a_{22})^{-1} e_{21}]\} + a_{21} b_{12} \{y_{21} + a_{21} [x_1 - (1 - a_{11})^{-1} e_{12}]\} \\ &= a_{12} [b_{21} y_{12} + b_{21} a_{12} (1 - a_{22})^{-1} y_{22}] + a_{21} [b_{12} y_{21} + b_{12} a_{21} (1 - a_{11})^{-1} y_{11}] \end{aligned} \quad (A12)$$

Derivation of equation (18)

$$\begin{aligned}
e_{12} + e_{21} - GDP_1 - GDP_2 &= e_{12} + e_{21} - v_1 x_1 - v_2 x_2 \\
&= v_1 [b_{11}y_{12} + b_{12}y_{22}] + 2v_1 [b_{12}y_{21} + b_{12}a_{21}(1-a_{11})^{-1}y_{11}] + v_2 [b_{21}y_{11} + b_{22}y_{21}] \\
&\quad + 2v_2 [b_{21}y_{12} + b_{21}a_{12}(1-a_{22})^{-1}y_{22}] + 2v_1 b_{12}a_{21}(1-a_{11})^{-1}e_{12} + 2v_2 b_{21}a_{12}(1-a_{22})^{-1}e_{21} \\
&\quad - v_1 (b_{11}y_{12} + b_{12}y_{22} + b_{12}y_{21} + b_{11}y_{11}) - v_2 (b_{21}y_{11} + b_{22}y_{21} + b_{21}y_{12} + b_{22}y_{22}) \\
&= 2v_1 [b_{12}y_{21} + b_{12}a_{21}(1-a_{11})^{-1}y_{11}] + 2v_2 [b_{21}y_{12} + b_{21}a_{12}(1-a_{22})^{-1}y_{22}] \\
&\quad + 2v_1 b_{12}a_{21}(1-a_{11})^{-1}e_{12} + 2v_2 b_{21}a_{12}(1-a_{22})^{-1}e_{21} - v_1 (b_{12}y_{21} + b_{11}y_{11}) - v_2 (b_{21}y_{12} + b_{22}y_{22}) \\
&= v_1 [b_{12}y_{21} + b_{12}a_{21}(1-a_{11})^{-1}y_{11}] + v_2 [b_{21}y_{12} + b_{21}a_{12}(1-a_{22})^{-1}y_{22}] \\
&\quad + 2v_1 b_{12}a_{21}(1-a_{11})^{-1}e_{12} + 2v_2 b_{21}a_{12}(1-a_{22})^{-1}e_{21} - (1-a_{11})^{-1}y_{11} - (1-a_{22})^{-1}y_{22}
\end{aligned} \tag{A13}$$

Appendix B

The derivation of gross exports accounting equation in G country N sector Model

B.1. The G-country, N-sector ICIO Model

Assume a world with G-countries, in which each country produces goods in N differentiated tradable sectors. Goods in each sector can be consumed directly or used as intermediate inputs, and each country exports both intermediate and final goods to all other countries.

All gross output produced by country s must be used as an intermediate good or a final good at home or abroad, or

$$X_s = \sum_r^G (A_{sr}X_r + Y_{sr}), \quad r, s = 1, 2, \dots, G \tag{B1}$$

Where X_s is the $N \times 1$ gross output vector of country s, Y_{sr} is the $N \times 1$ final demand vector that gives demand in country r for final goods produced in s, and A_{sr} is the $N \times N$ IO coefficient matrix, giving intermediate use in r of goods produced in s.

The G-country, N-sector production and trade system can be written as an ICIO model in block matrix notation

$$\begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_G \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1G} \\ A_{21} & A_{22} & \cdots & A_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ A_{G1} & A_{G2} & \cdots & A_{GG} \end{bmatrix} \begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_G \end{bmatrix} + \begin{bmatrix} Y_{11} + Y_{12} + \cdots + Y_{1G} \\ Y_{21} + Y_{22} + \cdots + Y_{2G} \\ \dots\dots\dots \\ Y_{G1} + Y_{G2} + \cdots + Y_{GG} \end{bmatrix}, \tag{B2}$$

and rearranging,

$$\begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_G \end{bmatrix} = \begin{bmatrix} I - A_{11} & -A_{12} & \cdots & -A_{1G} \\ -A_{21} & I - A_{22} & \cdots & -A_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ -A_{G1} & -A_{G2} & \cdots & I - A_{GG} \end{bmatrix}^{-1} \begin{bmatrix} \sum_r^G Y_{1r} \\ \sum_r^G Y_{2r} \\ \vdots \\ \sum_r^G Y_{Gr} \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} & \cdots & B_{1G} \\ B_{21} & B_{22} & \cdots & B_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ B_{G1} & B_{G2} & \cdots & B_{GG} \end{bmatrix} \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_G \end{bmatrix} \quad (B3)$$

where B_{sr} denotes the $N \times N$ block Leontief inverse matrix, which is the total requirement matrix that gives the amount of gross output in producing country s required for a one-unit increase in final demand in destination country r . Y_s is a $N \times 1$ vector that gives the global use of s ' final goods.

B.2. Value-added share by source matrix

Let V_s be the $1 \times N$ direct value-added coefficient vector. Each element of V_s gives the ratio of direct domestic value added in total output for country s . This is equal to one minus the intermediate input share from all countries (including domestically produced intermediates):

$$V_s = u(I - \sum_r^G A_{rs}), \quad (B4)$$

Define V , the $G \times GN$ matrix of direct domestic value added for all countries,

$$V = \begin{bmatrix} V_1 & 0 & \cdots & 0 \\ 0 & V_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & V_G \end{bmatrix}. \quad (B5)$$

Multiplying these direct value-added shares with the Leontief inverse matrices produces the $G \times GN$ value-added share (VB) matrix as equation (27) in the main text, it has the property:

$$\sum_s^G V_s B_{sr} = u. \quad (B6)$$

B.3. Decomposition of gross exports

Let E_{sr} be the $N \times 1$ vector of gross bilateral exports from s to r .

$$E_{sr} \equiv A_{sr} X_r + Y_{sr} \quad \text{for } s \neq r \quad (B7)$$

A country's gross exports to the world equal

$$E_{s*} = \sum_{r \neq s}^G E_{sr} = \sum_{r \neq s}^G (A_{sr} X_r + Y_{sr}) \quad (\text{B8})$$

From equation (29) in the main text we know that

$$\sum_{r=1}^G \sum_{g=1}^G B_{sg} Y_{gr} = \sum_{r=1}^G X_{sr} = X_s \quad (\text{B9})$$

Therefore, following identity holds

$$V_s X_s \equiv V_s \sum_{r=1}^G \sum_{g=1}^G B_{sg} Y_{gr} \quad (\text{B10})$$

Multiplying both sides of (B8) by (B6), we have

$$u E_{s*} (V_s B_{ss} + \sum_{t \neq s}^G V_t B_{ts}) E_{s*} = V_s B_{ss} \sum_{r \neq s}^G (A_{sr} X_r + Y_{sr}) + \sum_{t \neq s}^G V_t B_{ts} \sum_{r \neq s}^G (A_{sr} X_r + Y_{sr}) \quad (\text{B11})$$

Now we add and subtract VT_{s*} , defined by equation (32) in the main text, to the first term on RHS of (B11). This gives

$$V_s B_{ss} E_{s*} = VT_{s*} + V_s B_{ss} \sum_{r \neq s}^G (A_{sr} X_r + Y_{sr}) - V_s \sum_{r \neq s}^G \sum_{g=1}^G B_{sg} Y_{gr} \quad (\text{B12})$$

Recall that $X_s = \sum_{r=1}^G (A_{sr} X_r + Y_{sr})$ as defined in (B1), inserting it together with equation (B9) into (B12) gives

$$V_s B_{ss} E_{s*} = VT_{s*} + V_s B_{ss} (X_s - A_{ss} X_s - Y_{ss}) - V_s (X_s - \sum_{g=1}^G B_{sg} Y_{gs}) \quad (\text{B13})$$

Where $X_s - A_{ss} X_s - Y_{ss}$ equals the difference between country s' gross output and gross output

sold in domestic market, i.e. what country s' gross exports to the world market; $X_s - \sum_{g=1}^G B_{sg} Y_{gs}$

equals the difference between country s' gross output and its gross output finally consumed at domestic market. By rearranging terms,

$$V_s B_{ss} E_{s*} = VT_{s*} + V_s [B_{ss} (I - A_{ss}) - I] X_s + V_s [\sum_{g=1}^G B_{sg} Y_{gs} - B_{ss} Y_{ss}] \quad (\text{B14})$$

Substitute $B_{ss} (I - A_{ss}) - I$ in equation (B14) by $\sum_{r \neq s}^G B_{sr} A_{rs}$ (the property of inverse matrix, see

equation (B19) below) we have

$$V_s B_{ss} E_{s^*} = V_s \sum_{r \neq s} \sum_{g=1}^G B_{sg} Y_{gr} + V_s \sum_{r \neq s} B_{sr} Y_{rs} + V_s \sum_{r \neq s} B_{sr} A_{rs} X_s \quad (B15)$$

Insert (B15) into (B11) and rearrange terms, we obtain equation (34) in the main text.

B.4. Further partition of equation (34)

The term that measures double counting by intermediate goods trade in equation (34) $(V_s \sum_{r \neq s} B_{sr} A_{rs} X_s)$ can be further split into two parts: one is part of the home country's domestic value-added that is first exported but finally returns home in its intermediate imports to produce final goods and consumed at home, the other is a pure double counting portion due to two way intermediate trade.

Using the relation $X_s = Y_{ss} + A_{ss} X_s + E_{s^*}$, it is easy to show that

$$X_s - (I - A_{ss})^{-1} Y_{ss} = (I - A_{ss})^{-1} E_{s^*}. \quad (B16)$$

$(I - A_{ss})^{-1} Y_{ss}$ is the gross output needed to sustain final goods that is both produced and consumed in country s, using domestically produced intermediate goods; deduct it from country s' total gross output, what left is the gross output needed to sustain country s' production of its gross exports. Therefore, the left hand side of equation (B16) has straightforward economic meanings. We can further show that

$$(I - A_{ss})^{-1} Y_{ss} = B_{ss} Y_{ss} - \sum_{r \neq s} B_{sr} A_{rs} (I - A_{ss})^{-1} Y_{ss} \quad (B17)$$

the last term in RHS of (B17) is the final gross output needed to sustain final goods that is both produced and consumed in country s, but using intermediate goods that was originated in country s but shipped to other countries for processing before being re-imported by the source country in its intermediate goods imports (gross output sold indirectly in domestic market).

Given (B17), it easy to see

$$V_s \sum_{r \neq s} B_{sr} A_{rs} X_s = V_s \sum_{r \neq s} B_{sr} A_{rs} (I - A_{ss})^{-1} Y_{ss} + V_s \sum_{r \neq s} B_{sr} A_{rs} (I - A_{ss})^{-1} E_{s^*} \quad (B18)$$

Equation (B17) can be proven by using the property of inverse matrix:

$$\begin{bmatrix} B_{11} & B_{12} & \dots & B_{1G} \\ B_{21} & B_{22} & \dots & B_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ B_{G1} & B_{G2} & \dots & B_{GG} \end{bmatrix} \begin{bmatrix} I - A_{11} & -A_{12} & \dots & -A_{1G} \\ -A_{21} & I - A_{22} & \dots & -A_{2G} \\ \vdots & \vdots & \ddots & \vdots \\ -A_{G1} & -A_{G2} & \dots & I - A_{GG} \end{bmatrix} \begin{bmatrix} I & 0 & \dots & 0 \\ 0 & I & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & I \end{bmatrix}$$

we therefore have

$$B_{ss}(I - A_{ss}) - I = \sum_{r \neq s}^G B_{sr} A_{rs} \quad (\text{B19})$$

Using (B19), we have

$$(I - A_{ss})^{-1} Y_{ss} + [B_{ss}(I - A_{ss}) - I](I - A_{ss})^{-1} Y_{ss} = B_{ss} Y_{ss} \quad (\text{B20})$$

This is also the proof of equation (40) in the main text.

Total Input		200	200		

Computation details:

The Gross exports decomposition matrix

$$\begin{bmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{bmatrix} = \begin{bmatrix} 2 & 0.67 \\ 0 & 1.33 \end{bmatrix} \begin{bmatrix} 30 & 20 \\ 70 & 80 \end{bmatrix} = \begin{bmatrix} 60 + 46.69 & 40 + 53.3 \\ 0 + 93.33 & 0 + 106.67 \end{bmatrix} = \begin{bmatrix} 106.7 & 93.3 \\ 93.3 & 106.7 \end{bmatrix}$$

The value-added production and trade matrix

$$VBY = \begin{bmatrix} 0.5 & 0 \\ 0 & 0.5 \end{bmatrix} \begin{bmatrix} 106.7 & 93.3 \\ 93.3 & 106.7 \end{bmatrix} = \begin{bmatrix} 53.3 & 46.7 \\ 46.7 & 53.3 \end{bmatrix}$$

Decomposition results based on equations (13) and (14)

	Terms in equation (13) &(14)	USA	CHN
Value-added exports	v1	20	46.7
	v2	26.7	0
Return home value	v3	23.3	0
	v4	0	0
	v5	0	0
Foreign Value	v6	0	23.3
	v7	0	0
	v8	0	0
Gross Exports	E	70	70
VAX ratio		0.67	0.67

Since there is no foreign value-added in USA's production, the 30 unit of domestic final demand are 100% its own value-added, just as its exports, so its GDP is equal to 100. For CHN, the value-added in its exports and domestic final consumption also sum to 100. Both countries have identical VAX ratios, but the reasons why value added exports smaller than the gross exports are different; For USA, due to some of its own value added that is initially exported returns home after being used as an intermediate input in CHN to produce final goods exports back to USA ; For CHN, due to its production for exports uses FV: intermediate goods from the USA which embeds USA's value added; The return home VA (23.3) is a true value added for USA's national account, part of its GDP, but it is a double counting in official trade statistics and from China's point of view.

$$\text{Gross exports: } E = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \\ 0 \end{bmatrix}$$

As an illustration, we list how our approach computes each of the terms (v1 through v9) for Country 5 (the country that exports to USA, not USA itself):

Term 1 (v1 in Country 5's gross exports):

$$V_5 \sum_{r \neq 5}^G B_{5r} Y_{5r} = 1/5 * 1 * (0 + 0 + 0 + 0 + 0) = 0$$

Term 2:

$$V_5 \sum_{r \neq 5}^G B_{5r} Y_{rr} = 1/5 * \begin{bmatrix} 0 & 0 & 0 & 0 & 5/15 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 15 \end{bmatrix} = 1$$

Term 3:

$$V_5 \sum_{r \neq 5}^G \sum_{t \neq 5, r}^G B_{5r} Y_{rt} = V_5 \sum_{r \neq 5}^G B_{5r} \sum_{t \neq 5, r}^G Y_{rt} = 1/5 * \begin{bmatrix} 0 & 0 & 0 & 0 & 5/15 \end{bmatrix} \begin{bmatrix} 0+0+0+0 \\ 0+0+0+0 \\ 0+0+0+0 \\ 0+0+0+0 \\ 0+0+0+0 \end{bmatrix} = 0$$

Term 4:

$$V_5 \sum_{r \neq 5}^G B_{5r} Y_{r5} = 1/5 * \begin{bmatrix} 0 & 0 & 0 & 0 & 5/15 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} = 0$$

Term 5:

$$V_5 \sum_{r \neq 5}^G B_{5r} A_{r5} (I - A_{55})^{-1} Y_{55} = 1/5 * \begin{bmatrix} 0 & 0 & 0 & 0 & 5/15 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 4/5 \\ 0 \end{bmatrix} * (1-0)^{-1} * 0 = 0$$

Term 6:

$$V_5 \sum_{r \neq 5}^G B_{5r} A_{r5} (I - A_{55})^{-1} E_{5*} = 1/5 * \begin{bmatrix} 0 & 0 & 0 & 0 & 5/15 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 4/5 \\ 0 \end{bmatrix} * (1-0)^{-1} * 5 = 0$$

Term 7:

$$\sum_{t \neq 5}^G \sum_{r \neq 5}^G V_t B_{t5} Y_{5r} = \sum_{t \neq 5}^G V_t B_{t5} \sum_{r \neq 5}^G Y_{5r} = \begin{bmatrix} 1 & 1/2 & 1/3 & 1/4 & 1/15 \end{bmatrix} \begin{bmatrix} 1/5 \\ 2/5 \\ 3/5 \\ 4/5 \\ 0 \end{bmatrix} * (0+0+0+0+0) = 0$$

Term 8:

$$\begin{aligned} \sum_{t \neq 5}^G \sum_{r \neq 5}^G V_t B_{t5} A_{5r} (I - A_{rr})^{-1} Y_{rr} &= \sum_{t \neq 5}^G V_t B_{t5} \sum_{r \neq 5}^G A_{5r} (I - A_{rr})^{-1} Y_{rr} \\ &= \begin{bmatrix} 1 & 1/2 & 1/3 & 1/4 & 1/15 \end{bmatrix} \begin{bmatrix} 1/5 \\ 2/5 \\ 3/5 \\ 4/5 \\ 0 \end{bmatrix} * (0*1*0 + 0*1*0 + 0*1*0 + 0*1*0 + 1/3*1*15) \\ &= 4/5 * 5 = 4 \end{aligned}$$

Term 9:

$$\begin{aligned} \sum_{t \neq 5}^G \sum_{r \neq 5}^G V_t B_{t5} A_{5r} (I - A_{rr})^{-1} E_{r*} &= \sum_{t \neq 5}^G V_t B_{t5} \sum_{r \neq 5}^G A_{5r} (I - A_{rr})^{-1} E_{r*} \\ &= \begin{bmatrix} 1 & 1/2 & 1/3 & 1/4 & 1/15 \end{bmatrix} \begin{bmatrix} 1/5 \\ 2/5 \\ 3/5 \\ 4/5 \\ 0 \end{bmatrix} * (0*1*1 + 0*1*2 + 0*1*3 + 0*1*4 + 1/3*1*0) \\ &= 4/5 * 0 = 0 \end{aligned}$$

Similarly, we can decompose other countries' gross exports, and obtain the results reported in the upper panel of table 1.

The ICIO Table for Case 2:

Input \ Output	Intermediate use						Final use						Total Output
	USA	C1	C2	C3	C4	C5	USA	C1	C2	C3	C4	C5	
USA	0	10	0	0	0	0	0	0	0	0	0	0	10
C1	0	0	11	0	0	0	0	0	0	0	0	0	11
C2	0	0	0	12	0	0	0	0	0	0	0	0	12
C3	0	0	0	0	13	0	0	0	0	0	0	0	13

C5	0	0	0	0	0	0	15	0	0	0	0	0	15
Value added	10	1	1	1	1	1							
Total input	10	11	12	13	14	15							

Computation details for case 2

$$\text{Direct input coefficient matrix: } A = \begin{bmatrix} 0 & 10/11 & 0 & 0 & 0 & 0 \\ 0 & 0 & 11/12 & 0 & 0 & 0 \\ 0 & 0 & 0 & 12/13 & 0 & 0 \\ 0 & 0 & 0 & 0 & 13/14 & 0 \\ 0 & 0 & 0 & 0 & 0 & 14/15 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\text{Direct value-added share: } A^v = \begin{bmatrix} 1 & 1/11 & 1/12 & 1/13 & 1/14 & 1/15 \end{bmatrix}$$

$$\text{Final demand matrix: } Y = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 15 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

Leontief Inverse: $B = \begin{bmatrix} 1 & 10/11 & 10/12 & 10/13 & 10/14 & 10/15 \\ 0 & 1 & 11/12 & 11/13 & 11/14 & 11/15 \\ 0 & 0 & 1 & 12/13 & 12/14 & 12/15 \\ 0 & 0 & 0 & 1 & 13/14 & 13/15 \\ 0 & 0 & 0 & 0 & 1 & 14/15 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$

Gross exports: $E = \begin{bmatrix} 10 \\ 11 \\ 12 \\ 13 \\ 14 \\ 15 \end{bmatrix}$

Again, we list how our approach computes each of the terms (v1 through v9) for Country 5 (the country that exports final goods to USA, the 6th in the trading sequence):

Term 1 (i.e., v1 in Country 5's gross exports):

$$V_6 \sum_{r \neq 6}^G B_{6r} Y_{6r} = 1/15 * 1 * (15 + 0 + 0 + 0 + 0) = 1$$

Term 2:

$$V_6 \sum_{r \neq 6}^G B_{6r} Y_{rr} = 1/15 * \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} = 0$$

Term 3:

$$V_6 \sum_{r \neq 6}^G \sum_{t \neq 6, r}^G B_{6r} Y_{rt} = V_6 \sum_{r \neq 6}^G B_{6r} \sum_{t \neq 6, r}^G Y_{rt} = 1/15 * \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 + 0 + 0 + 0 \\ 0 + 0 + 0 + 0 \\ 0 + 0 + 0 + 0 \\ 0 + 0 + 0 + 0 \\ 15 + 0 + 0 + 0 \end{bmatrix} = 0$$

Term 4:

$$V_6 \sum_{r \neq 6}^G B_{6r} Y_{r6} = 1/15 * \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} = 0$$

Term 5:

$$V_6 \sum_{r \neq 6}^G B_{6r} A_{r6} (I - A_{66})^{-1} Y_{66} = 1/15 * \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 14/15 & 0 & 0 & 0 & 0 \end{bmatrix} * (1-0)^{-1} * 0 = 0$$

Term 6:

$$V_6 \sum_{r \neq 6}^G B_{6r} A_{r6} (I - A_{66})^{-1} E_{6*} = 1/15 * \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 14/15 & 0 & 0 & 0 & 0 \end{bmatrix} * (1-0)^{-1} * 15 = 0$$

Term 7:

$$\sum_{t \neq 6}^G \sum_{r \neq 6}^G V_t B_{t6} Y_{6r} = \sum_{t \neq 6}^G V_t B_{t6} \sum_{r \neq 6}^G Y_{6r} = \begin{bmatrix} 1 & 1/11 & 1/12 & 1/13 & 1/14 \end{bmatrix} \begin{bmatrix} 10/15 \\ 11/15 \\ 12/15 \\ 13/15 \\ 14/15 \end{bmatrix} * (15 + 0 + 0 + 0 + 0) = 14$$

Term 8:

$$\begin{aligned} \sum_{t \neq 6}^G \sum_{r \neq 6}^G V_t B_{t6} A_{6r} (I - A_{rr})^{-1} Y_{rr} &= \sum_{t \neq 6}^G V_t B_{t6} \sum_{r \neq 6}^G A_{6r} (I - A_{rr})^{-1} Y_{rr} \\ &= \begin{bmatrix} 1 & 1/11 & 1/12 & 1/13 & 1/14 \end{bmatrix} \begin{bmatrix} 10/15 \\ 11/15 \\ 12/15 \\ 13/15 \\ 14/15 \end{bmatrix} * (0*1*0 + 0*1*0 + 0*1*0 + 0*1*0 + 0*1*0) = 0 \end{aligned}$$

Term 9:

$$\begin{aligned} \sum_{t \neq 6}^G \sum_{r \neq 6}^G V_t B_{t6} A_{6r} (I - A_{rr})^{-1} E_{r*} &= \sum_{t \neq 6}^G V_t B_{t6} \sum_{r \neq 6}^G A_{6r} (I - A_{rr})^{-1} E_{r*} \\ &= \begin{bmatrix} 1 & 1/11 & 1/12 & 1/13 & 1/14 \end{bmatrix} \begin{bmatrix} 10/15 \\ 11/15 \\ 12/15 \\ 13/15 \\ 14/15 \end{bmatrix} * (0*1*10 + 0*1*11 + 0*1*12 + 0*1*13 + 0*1*14) = 0 \end{aligned}$$

Similarly, we can decompose other countries' gross exports, and obtain the results reported at the lower panel of table 1

Appendix D: Detailed numerical example of a two country supply chain¹

We now consider an example in which both countries export (and import) intermediate goods in an inter-country supply chain. This example will show our accounting equation can decompose a country's gross exports into various value-added and double counted components in a way that is consistent with one's intuition. We will also illustrate why and how our estimate of VS1* in such a case differs from Daudin et al, why and how our estimate of the share of domestic value-added (GDP) in exports differs from Johnson and Noguera's value-added to gross exports ratio, and why and how our estimate of foreign value-added (GDP) in exports differs from HIY's VS measure but our foreign content in exports generalizes it.

Suppose the world production and trade take place in five stages (in a year) as summarized by Table D1. In Stage 1, perhaps a design stage, Country 1 uses labor to produce a unit of Stage-1 output. This is exported to Country 2 as an input to Stage-2 production. In Stage 2, Country 2 adds a unit of labor to produce 2 units of Stage-2 output which are shipped back to country 1 as an input to Stage-3 production. Country 1 adds another unit of labor to produce 3 units of Stage-3 output which are then exported to country 2 as an input to Stage-4 production. In Stage 4, country 2 adds a unit of labor to produce 4 units of Stage-4 output which are shipped back to country 1 as an input to Stage-5 production. The Stage-5 output is the final good. 3 units of the final good are exported to country 2, and 2 units are absorbed domestically in country 1.

Suppose each unit of intermediate and final goods is worth \$1. The total output in country 1 is \$9, in country 2 is \$6, the total value added (labor inputs) in the two countries is \$3 and \$2 respectively. The total exports from 1 to 2 and from 2 to 1 are \$7 and \$6, respectively; and the exports of final goods from 1 to 2 and 2 to 1 are \$3 and \$0 respectively.

For this simple example of an international supply chain, we can decompose both countries' gross exports into value-added and double counted components by intuition without using any equations. The intuitive decomposition is summarized in Table D2. We will then verify that our exports decomposition formula produces exactly the same results.

¹ We are grateful to Peter Dixon and Maureen Rimmer for helping us to develop this instructive example.

Table D1 A two country supply-chain

	Country 1				Country 2			
	Final Demand	Labor input	Imported input	Output	Imported input	Labor input	Output	Final Demand
Stage 1 in		\$1						
Stage 1 out				\$1				
Stage 2 in					\$1	\$1		
Stage 2 out							\$2	
Stage 3 in		\$1	\$2					
Stage 3 out				\$3				
Stage 4 in					\$3	\$1		
Stage 4 out							\$4	
Stage 5 in		\$1	\$4					
Stage 5 out				\$5				
	\$2							\$3
Total	\$2	\$3	\$6	\$9	\$4	\$2	\$6	\$3

We proceed as follows: Starting from the last stage (Stage 5), each country contributes \$2 of value-added with their (previously produced) intermediate inputs, and Country 1 contributes an additional \$1 of labor input to produce a total of 5 units of the final good. We assume labor is homogenous across countries. Since 2 units of the final good stay in Country 1 and 3 units are consumed in Country 2, all the value-added embodied in intermediate inputs that are eventually absorbed by each country should be split as 40% for country 1 and 60% for country 2, in proportion to the units of the final good consumed by the two countries. Therefore, the total value added exports from Country 1 to 2 are $0.6 \times \$3 = \1.8 (which is recorded in the cell in row “total” and column 2a of Table D2). Similarly, Country 2’s exports of value added to 1 are $0.4 \times \$2 = \0.8 (which is recorded in the cell in row “total” and column 2b). Out of Country 1’s \$7 of gross exports, the total amount of double counting, or the difference between its gross exports and its value-added exports is \$5.2 ($=\$7 - \1.8). This is recorded in the cell in row “total” and column 7a. Similarly, out of Country 2’s \$6 of gross exports, the total amount of double counting is $\$6 - \$0.8 = \$5.2$, which is recorded in the cell in row “total” and column (7b).

The beauty of this simple example is that we can work out the structure of the double counted values by intuition. Given what happens in Stage 5, we can split a country’s value added in production in each of the earlier stages into the sum of value-added exports in that stage (that is ultimately absorbed abroad) and the value added that is exported in that stage but returns home next stage as part of its imports from the foreign country. Then the amount of exports in

each of the first 4 stages that are double counted can be computed as each stage's gross output minus value added exports in that stage. In Stage 1, Country 1's domestic value added is \$1 (recorded in the cell (S1, 1a)). Since we know by Stage 5, 40% of the final good stays in Country 1, and 60% is exported to Country 2, we can split the \$1 of domestic value added into \$0.6 of Country 1's exports of value added (recorded in the cell (S1, 2a)) and \$0.4 of the domestic value added that returns home in the next stage and eventually consumed at home in Stage 5 (recorded in (S1, 3a)). Out of Country 1's gross exports of \$1 in Stage 1, the total double counted amount is the difference between its gross exports and value added exports, or $\$1 - \$0.6 = \$0.4$, as recorded in (S1, 7a). In Stage 2, Country 2 uses \$1 of intermediate good from Country 1 as an input together with its additional \$1 of labor to produce \$2 exports. Its domestic value added is \$1 (recorded in (S2, 1b)). Again, since we know the split of the final good consumption in the two countries in Stage 5, we can split Country 2's domestic value added into \$0.4 of its exports of value added (recorded in (S2, 2b)) and \$0.6 of domestic value added that will return home in Stage 3 and eventually consumed at home in Stage 5 (recorded in S2, 4b)). Recall that out of \$1 of intermediate good that Country 2 imports from Country 1, \$0.4 will go back to Country 1 and be consumed there eventually. This is recorded in (S2, 5b), which is numerically identical to (S1, 3a). The remaining \$0.6 is double counted intermediate goods, and is recorded in (S2, 6b). This can also be verified in the following way. Since we know Country 2's gross exports in Stage 2 is \$2 but its value added exports are only \$0.4, the total amount of double counting in this stage's gross exports must be the difference between the two, or \$1.6 as recorded in (S2, 7b). Therefore, the "pure double counted" portion of foreign intermediate good has to equal $\$1.6 \text{ (S2, 7b)} - \$0.6 \text{ (S2, 3b)} - \$0.4 \text{ (S2, 5b)}$, which equals to \$0.6, as recorded in (S2, 6b). This amount represents the part of Country 1's Stage 1 intermediate good exports that cross borders more than twice before it can be embed in the final goods for consumption.

In Stage 3, Country 1 uses \$2 of imported intermediate goods from Country 2 as an input with its additional \$1 of labor to produce \$3 exports. Country 1's domestic value added is \$1 (S3, 1a). Again, because 60% of the final good will be eventually absorbed in the foreign country, the \$1 of domestic value added can be split into \$0.6 of Country 1's exports of value added (S3, 2a) and \$0.4 of the domestic value added that is exported in Stage 3 but will return in Stage 4 and eventually consumed there in Stage 5 (S3, 3a). Furthermore, the Stage 3 production does use imported intermediate good from the previous stage. The amount of foreign value added

embedded in its intermediate good imported from Country 2 that is not pure double counting should be the same as Country 2's domestic value added that is sent to Country 1 in Stage 2 but returns home and will be eventually absorbed there. We know that amount is \$0.6 (S2, 3b). Therefore, the amount of foreign value added that is used in Country 1's Stage 3 production for exports and that will be eventually absorbed in Country 2 should be the same as \$0.6 in (S3, 5a).

Because the value of Country 1's stage 1 exports (\$1) is already counted three times by the time Stage 3 exports take place, we record that amount as a pure double counting item in (S3, 4a). Since we know out of \$3 of Country 1's gross exports in Stage 3, only \$0.6 is exports of value added that will eventually be absorbed abroad, $\$3 - \$0.6 = \$2.4$ represents the total amount of double counting in this stage's gross exports, and is recorded in (S3, 7a). Out of the \$1 foreign value added from Stage 2, since the amount that will go back to the foreign country and is absorbed there is 0.6 (S3, 5a), the amount of pure double counting must be $\$1 - \$0.6 = \$0.4$, as recorded in (S3, 6a).

One way to check the sensibility of our reasoning is to compare the total amount of double counting in Stage-3 gross exports with the sum of the double counted components. Out of Country 1's \$3 of gross exports in Stage 3, we know the total amount of double counting is \$2.4 (recorded in (S3, 7a)). We can check that the sum of the double counted components in Country 1's exports in this stage (the sum of (S3, 3a), (S3, 4a), (S3, 5a), and (S3, 6a)) is also \$2.4.

We now move to Stage 4, when Country 2 combines \$1 of domestic value (recorded in (S4, 1b)) with \$3 of intermediate goods imported from Country 1 in the previous stage, and exports \$4 of intermediate goods in gross terms to Country 1. Given that 40% of the final good will be absorbed in Country 1 by stage 5, we can split Country 2's \$1 domestic value added in this stage into \$0.4 which is Country 2's value added exports (S4, 2b), and \$0.6 which is the amount of its domestic value added that will return home in Stage 5 and be absorbed at home (S4, 3b). Country 2's gross exports in this stage also contain 40% of Country 1's value added from the previous stage, recorded as \$0.4 in (S4, 5b).

Table D2 Intuitive accounting for the gross export flows in the two country supply chain

	From Country 1's Viewpoint							From Country 2's Viewpoint						
	Domestic Value-added In exports	A Value-added exports	Previous Intermediate exports returning home		Foreign intermediate imports		Total double counted intermediate in exports	Domestic Value-added in exports	Value-added exports	Previous Intermediate exports returning home		Foreign intermediate imports		Total double counted intermediate in exports
			DV	Pure Double counting	FV	Pure Double counting				DV	Pure Double counting	FV	Pure Double counting	
	(1a)	(2a)	(3a)	(4a)	(5a)	(6a)	(7a)	(1b)	(2b)	(3b)	(4b)	(5b)	(6b)	(7b)
Stage 1 (S1): Country 1 exports and Country 2 imports	1	0.6	0.4	0	0	0	0.4							
Stage 2 (S2): Country 2 exports and Country 1 imports								1	0.4	0.6	0	0.4	0.6	1.6
Stage 3 (S3): Country 1 exports and Country 2 imports	1	0.6	0.4	1	0.6	0.4	2.4							
Stage 4 (S4): Country 2 exports and Country 1 imports								1	0.4	0.6	1	0.4	1.6	3.6
Stage 5 (S5): Country 1 exports and Country 2 imports	0.6 ^a	0.6	0	1.2	0.6	0.6	2.4							
Total	2.6	1.8	0.8	2.2	1.2	1	5.2	2	0.8	1.2	1	0.8	2.2	5.2
Terms in Table D4 that correspond to the previous row	DV ₁	v1+v2	v3+v4	v5	v6+v7	v8	Sum of v3 to v8	DV ₂	v1+v2	v3+v4	v5	v6+v7	v8	Sum of v3 to v8

Note: a. In stage 5, because Country 1 exports 3 units of the final goods and keeps 2 units at home, 40% of Country 1's domestic value added (or \$0.4) in that stage stays home, and 60% of it (or \$0.6) is its exports of value added to Country 2. The last row shows the concordance between the second to the last row of this table and the decomposition results reported in Table D4 that are derived from our gross exports accounting equations. The gross exports accounting equations (13) and (14) provide the final decomposition results as the total row in the table, not the intermediate iteration in each the stage.

By symmetry, the pure double counting amount in (S4, 4b) must be the same as (S3, 4a), which is \$1. Let us next work out the pure double counting term in (S4, 6b). First, out of Country 2's \$4 gross exports in Stage 4, only \$0.4 is value added exports, we know the total amount of double counting must be \$3.6, which is recorded in (S4, 7b). Second, we also know \$3.6 of the total amount of double counting must be equal to the sum of the double counted components, or the sum of (S4, 3b), (S4, 4b), (S4, 5b) and (S4, 6b). This implies that (S4, 6b) should be \$1.6. The economic meaning of (S4, 6b) is repeated double counting of the intermediate goods that have been double counted in previous rounds of trade.

We now go to Stage 5. Because this is the final stage in which the final good is produced by Country 1 but distributed 40% and 60% in Countries 1 and 2, respectively, we record the values somewhat differently from the earlier stages (when the entire production was exported). While Country 1's domestic value added in the production is \$1 in this stage, only 60% of the final good is exported. So we record the amount of domestic value-added in Country 1's exports as \$0.6 (S5, 1a). The amount of Country 1's value added exports (that is absorbed in Country 2) is also \$0.6, as recorded in (S5, 2a).

Since Stage 5 production uses imported intermediate good from the previous stage, it embeds foreign value added from Stage 4. The amount of foreign value added from Stage 4 that is used in Country 1's Stage 5 production and eventually absorbed in the foreign country is proportional to the amount of the final good that is exported from Country 1 to 2. This means (S5, 5a) is \$0.6. This of course is the same value as in (S4, 3b).

To determine the value in (S5, 4a), we note that the total value added from Country 1 in the first and the 3rd stages are \$1. Both values are counted as part of Country 2's intermediate exports in Stage 4. Since only 60% of the final good are exported, the pure double counting associated with the domestically produced intermediate goods in the previous stages is $2 \times 0.6 = \$1.2$.

To determine the value of (S5, 6a), we first note that the total amount of double counting in Stage 5 exports is the difference between the value of gross exports in that stage (\$3) and the value added exports in that stage (\$0.6), which is \$2.4, as recorded in (S5, 7a). The value in (S5, 6a) would simply be the difference between \$2.4 and the sum of the values in (S5, 2a), (S5, 4a), and (S5, 5a), which yields \$0.6. The amount in (S5, 6a) represents the value that is originally

created in Country 2 but has been counted multiple times beyond the value added of Country 2 already assigned to Countries 1 and 2.

We can check the sensibility of the discussion by summing over the values across the five stages. For example, when we sum up the values over all stages in Column (2a), we obtain 1.8, which is exactly the amount of Country 1’s value added exports that we intuitively think should be. Summing up the values in Column (7a) across the five stages yields \$5.2, which is the same as what we obtain intuitively earlier.

Separately, we can apply our decomposition formula and generate the measurements of the same set of economic concepts. To do so, we note that the five stages in this example are best represented by 5 sectors (e.g., car windows, paint on a car, rubber tires on a car and a whole car are considered in separate sectors), because an input output table is built on the assumption that all goods within a sector are homogenous, i.e the input-output and direct value-added coefficients are the same for all products within a sector. In our example, because different stages of the production have different direct value-added and IO coefficients, we have to treat the five stages as five different sectors.

The inter-country supply chain data in table D1 can be summarized by the following Input -output IO table:

Table D3 IO table constructed from two-country Supply Chain data

Input			Output	Intermediate use					Final use		Total output
			Country 1			Country 2		Country 1	Country 2		
			Sector 1	Sector 2	Sector 3	Sector 1	Sector 2				
Intermediate input	Country 1	Sector 1				1				1	
		Sector 2					3			3	
		Sector 3						2	3	5	
	Country 2	Sector 1		2						2	
		Sector 2			4					4	
Value-added			1	1	1	1	1				
Total Input			1	3	5	2	4				

Note: an input -output table is built on homogenous products assumption, i.e input-output and direct value-added coefficients are the same for each product/industry. In order to use an input-output model, each stage of production has to be treated as a distinct product/industry because different stages of the production has different direct value-added and IO coefficients.

From table D3, we can obtain following matrixes:

$$A = \begin{bmatrix} 0 & 0 & 0 & 1/2 & 0 \\ 0 & 0 & 0 & 0 & 3/4 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 2/3 & 0 & 0 & 0 \\ 0 & 0 & 4/5 & 0 & 0 \end{bmatrix}$$

$$\text{In } A, \quad a_{11} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad a_{12} = \begin{bmatrix} 1/2 & 0 \\ 0 & 3/4 \\ 0 & 0 \end{bmatrix}, \quad a_{21} = \begin{bmatrix} 0 & 2/3 & 0 \\ 0 & 0 & 4/5 \end{bmatrix}, \quad a_{22} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

Value-added coefficient:

$$v_1 = [1 \quad 1/3 \quad 1/5], \quad v_2 = [1/2 \quad 1/4]$$

Final goods and exports

$$y_{11} = \begin{bmatrix} 0 \\ 0 \\ 2 \end{bmatrix}, \quad y_{12} = \begin{bmatrix} 0 \\ 0 \\ 3 \end{bmatrix}, \quad y_{21} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad y_{22} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad e_{12} = \begin{bmatrix} 1 \\ 3 \\ 3 \end{bmatrix}, \quad e_{21} = \begin{bmatrix} 2 \\ 4 \end{bmatrix}$$

Leontief inverse $B = (I - A)^{-1}$

$$B = \begin{bmatrix} 1 & 1/3 & 1/5 & 1/2 & 1/4 \\ 0 & 1 & 3/5 & 0 & 3/4 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 2/3 & 2/5 & 1 & 1/2 \\ 0 & 0 & 4/5 & 0 & 1 \end{bmatrix}$$

$$\text{In } B, \quad b_{11} = \begin{bmatrix} 1 & 1/3 & 1/5 \\ 0 & 1 & 3/5 \\ 0 & 0 & 1 \end{bmatrix}, \quad b_{12} = \begin{bmatrix} 1/2 & 1/4 \\ 0 & 3/4 \\ 0 & 0 \end{bmatrix}, \quad b_{21} = \begin{bmatrix} 0 & 2/3 & 2/5 \\ 0 & 0 & 4/5 \end{bmatrix}, \quad b_{22} = \begin{bmatrix} 1 & 1/2 \\ 0 & 1 \end{bmatrix}$$

$$\text{And } (1 - a_{11})^{-1} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad (1 - a_{22})^{-1} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

Equations (13) and (14) can be converted to a 5-sector version easily by defining each of their terms in a matrix with proper dimensions. The formula in Equations (13) then allows us to decompose Country 1's gross exports as follows:

$$v1 = v_1 b_{11} y_{12} = \begin{bmatrix} 1 & 1/3 & 1/5 \\ 1 & 1/3 & 1/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 3 \end{bmatrix} = \begin{bmatrix} 1 & 2/3 & 3/5 \\ 1 & 2/3 & 3/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 3 \end{bmatrix} = 1.8$$

$$v2 = v_1 b_{12} y_{22} = \begin{bmatrix} 1/2 & 1/4 \\ 1 & 1/3 & 1/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} = 0$$

$$v3 = v_1 b_{12} y_{21} = \begin{bmatrix} 1/2 & 1/4 \\ 1 & 1/3 & 1/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} = 0$$

$$v4 = v_1 b_{12} a_{21} (1 - a_{11})^{-1} y_{11} = \begin{bmatrix} 1/2 & 1/4 \\ 1 & 1/3 & 1/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1/2 & 1/4 \\ 0 & 3/4 \\ 0 & 0 & 4/5 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 2 \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1/3 & 2/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 2 \end{bmatrix} = 0.8$$

$$v5 = v_1 b_{12} a_{21} (1 - a_{11})^{-1} e_{12} = \begin{bmatrix} 1/2 & 1/4 \\ 1 & 1/3 & 1/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1/2 & 1/4 \\ 0 & 3/4 \\ 0 & 0 & 4/5 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 3 \\ 3 \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1/3 & 2/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 3 \\ 3 \end{bmatrix} = 2.2$$

$$v6 = v_2 b_{21} y_{12} = \begin{bmatrix} 1/2 & 1/4 \\ 0 & 2/3 & 2/5 \\ 0 & 0 & 4/5 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 3 \end{bmatrix} = \begin{bmatrix} 0 & 1/3 & 2/5 \\ 0 & 1/3 & 2/5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 3 \end{bmatrix} = 1.2$$

$$v7 = v_2 b_{21} a_{12} (1 - a_{22})^{-1} y_{22} = \begin{bmatrix} 1/2 & 1/4 \\ 0 & 2/3 & 2/5 \\ 0 & 0 & 4/5 \end{bmatrix} \begin{bmatrix} 1/2 & 0 \\ 0 & 3/4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \end{bmatrix} = 0$$

$$\begin{aligned}
v8 &= v_2 b_{21} a_{12} (1 - a_{22})^{-1} e_{21} = \begin{bmatrix} 1/2 & 1/4 \end{bmatrix} \begin{bmatrix} 0 & 2/3 & 2/5 \\ 0 & 0 & 4/5 \end{bmatrix} \begin{bmatrix} 1/2 & 0 \\ 0 & 3/4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 2 \\ 4 \end{bmatrix} \\
&= \begin{bmatrix} 0 & 1/3 & 2/5 \end{bmatrix} \begin{bmatrix} 1/2 & 0 \\ 0 & 3/4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 2 \\ 4 \end{bmatrix} = 1
\end{aligned}$$

Similarly, we can also decompose country 2's gross exports into the 8 terms specified in equation (14). We summarize all the computation in table D4. It can be checked easily that the numbers in Table D4 generated by our formula match exactly with the corresponding ones that one can intuitively work out in Table D2. In particular, Country 1's value added exports (that are absorbed abroad) from our formula in Table D4 are \$1.8, exactly as that in Table D2. In comparison, the total domestic value added in Country 1's exports (that does not exclude exported value added that returns home but does exclude the pure double counted term) is \$2.6. This example confirms our theoretical discussion that value-added exports are generally smaller than domestic value-added (GDP) in exports and domestic content in exports. If one is interested in the share of domestic value added in a country's exports, then the VAX ratio is not the right metric.

From Table D4, the VS measure produced by our decomposition formula (13) is 2.2. The intuitive discussion in connection with Table D2 illustrates why we argue that the VS measure is not a 'net' concept and is not equal to foreign value added in a country's gross exports. The fundamental reason is that the VS measure has to include some pure double counted terms. (Again, these pure double counting terms would disappear if we use the HIY assumption that at least one of the countries does not export intermediate good.)

The more intermediate trade crosses border, the larger these double counted foreign intermediates imports are. With two-way intermediate trade, the part of foreign GDP that is embodied in the home country's gross exports will always be smaller than the VS measure. Relative to the original VS measure, our generalized measure includes double counted intermediate exports produced by the foreign country that may cross border several times (v8). The numerical results also show HIY's convention that a country's gross exports is equal to

domestic content plus vertical specialization is also maintained by our accounting equation (as long as one defines domestic content and vertical specialization appropriately).

Finally, this example also shows that if one only considers returning domestic value-added in final goods, while excluding domestic content returning home via intermediate goods imports, such as Daudin et al (2011), then one would under-estimate VS1*. In this example, if one applies Daudin et al's narrow definition of VS1*, it would be zero as indicated by v3 in Table D4. If one also includes returning domestic value added in intermediate good and a pure double counting term, VS1* would become \$3 instead. Our redefined measure of VS1* is more complete.

Table D4 Gross exports decomposition based on our accounting equation

Terms in accounting equation	E12	E21
$v1 = v_1 b_{11} y_{12}$	1.8	0
$v2 = v_1 b_{12} y_{22}$	0	0.8
$v3 = v_1 b_{12} y_{21}$	0	1.2
$v4 = v_1 b_{12} a_{21} (1 - a_{11})^{-1} y_{11}$	0.8	0
$v5 = v_1 b_{12} a_{21} (1 - a_{11})^{-1} e_{12}$	2.2	1
$v6 = v_2 b_{21} y_{12}$	1.2	0
$v7 = v_2 b_{21} a_{12} (1 - a_{22})^{-1} y_{22}$	0	0.8
$v8 = v_2 b_{21} a_{12} (1 - a_{22})^{-1} e_{21}$	1	2.2
E=Gross exports (sum v1 to v8)	7	6
VT=Value-added exports (sum of v1 and v2)	1.8	0.8
DV=Domestic value-added in gross exports (sum of v1 to v4)	2.6	2
FV=Foreign value-added in gross exports (v6+v7)	1.2	0.8
DC=Domestic content in gross exports (sum of v1 to v5)	4.8	3.0
Double counted home country's intermediate exports	2.2	1
Double counted foreign country's intermediate exports	1	2.2
VS=Vertical specialization(sum v6 to v8) = $v_i b_{i2}$	2.2	3
VS1* measure defined in this paper (sum v3 to v5)	3	2.2
VS1* measure defined in Daudin, et al. (v3 only)	0	1.2
Johnson & Noguera's VAX ratio	0.257	0.133
Share of domestic value-added in gross exports	0.371	0.333
Share of domestic content in gross exports = $v_i b_{i1}$	0.686	0.5

Appendix E Detailed results of magnification of trade costs by multi-stage production

As discussed in section 4.2 in the main text, our gross export accounting method provides an ideal way to re-examine the magnification effect of trade cost by multi-stage production. In Table E1, we first report standard tariffs (on a country's exports) in columns (1a). These are trade-weighted tariff rate applied by a country's trading partners (in ad-valorem equivalent). Column (2a) reports the share of imported content in final goods exports. These imported intermediate inputs are used to produce final goods exports, and so incur multiple tariffs charges. These tariff rates on the imported inputs (as a share of f.o.b. export value) are presented in columns (3a); they are trade-weighted average tariffs for intermediate inputs from the other 25 countries/regions in our database that are used in the exporting country to produce final goods exports. The sum of the two tariffs is reported in Column (4a).

Columns (5a) reports our illustrative calculation of the first order magnification effect of using imported intermediate inputs to produce exports. It represents the magnification effect if tariffs were the only factor that augments the trading costs. For instance, one additional stage of production increases trade costs of Vietnam's merchandise production by 80% of its standard tariff.

Although the number is already quite high for a number of countries, these values still represent only the lower bound of the true multi-stage tariff charge. First, in this illustration, we only consider two stages of production, while in the real world, these inputs may have already crossed multiple borders before reaching the final exporter. Second, we ignore transport costs in this example, but transport costs are also magnified as intermediate goods cross multiple borders.

The second magnification force occurs because tariffs are applied to gross export values instead of the value added in the direct exporting country. Table E1 also reports the magnification ratio of the "effective" tariff rate to the standard tariff rate. Column (6a) reports the effective tariff rate, which equals the standard tariff rate in column (2a) divided by the domestic content share (which is 1 minus column (2a)) and weighted by trade. Column (7a) reports the implied magnification ratio due to the presence of vertical specialization. These effects are generally larger than the tariff magnification factor reported in column (5a).

Generally speaking, tariffs play a large role in the magnification of trade costs in the presence of GVCs for emerging market economies, while they play a smaller role for most developed countries. The fact that the domestic value added share in emerging economies' merchandise exports is usually lower than that in developed countries tends to amplify the effective trade cost for developing countries. As an implication, reducing tariffs and nontariff barriers in manufacturing sectors globally is fully consistent with the interest of emerging market economies because it lowers the cost of GVC participation for developing countries. Lowering "own" tariffs on intermediate inputs for domestic manufacturing production would significantly reduce the magnification effects as demonstrated in column (5), while lowering such tariffs in other countries would significantly reduce the effective rate of protection, as seen in columns (6) and (7), due to the lower domestic value-added share in most developing countries' manufacturing exports.

To see if the end-use classifications and the proportionality assumption produce different results, we go through the same set of calculation but using the proportionality assumption to construct our data set. All the estimates in Columns (1b), (2b), ..., (7b) are the direct counterparts to Columns (1a), (2a), ..., (7a). In Column 8, we report the difference in terms of % of each country's gross exports for the magnification factor computed using the two different databases. For Indonesia, Malaysia, and China, the BEC method produces a larger magnification effect. In comparison, for Canada, India, and Mexico, the BEC method produces a smaller magnification effect. In general, which method we use makes a difference.

Table E1 Magnification of trade costs on final goods exports from vertical specialization, 2004

Country or region	Database produced by BEC classification							Database produced by proportion assumption							100* difference	
	Standard Tariff	Foreign content share (VS)	Tariff on imported inputs	two stage tariffs 1a+3a	Magnification factor 4a/1a	Effective tariff rate	Magnification ratio 6a/1a	Standard Tariff	Foreign content share (VS)	Tariff on imported inputs	two stage tariffs 1b+3b	Magnification factor 4b/1b	Effective tariff rate	Magnification ratio 6b/1b	Magnification factor 5a-5b	Magnification ratio 7a-7b
	(1a)	(2a)	(3a)	(4a)	(5a)	(6a)	(7a)	(1b)	(2b)	(3b)	(4b)	(5b)	(6b)	(7b)	(8)	(9)

Appendix F The difference between bilateral trade imbalance in gross and value-added terms

Figure F1 provides a scatter plot of the trade balance in value added terms against the trade balance in standard trade statistics for all bilateral country pairs in our ICIO database. Without loss of generality, the two countries in any pair are always ordered in such a way that the trade balance in gross terms is non-negative. A negative value-added to gross BOT ratio indicates there is a sign change between BOT measured in gross and value-added terms. All observations that lie below the 45 degree line have their bilateral trade imbalance smaller in value-added terms than those in gross terms, and vice visa for observations that lie above the 45 degree line.

Zooming in near the origin shows that the trade balances of a number of country pairs even have opposite signs measured in value-added and gross terms. For example, Japan's trade balance vis-à-vis China is switched from a surplus in gross trade terms to a deficit in value added terms. This is consistent with the notion that a significant part of Japan's exports to China are components used by China-based firms for exports to the United States, the European Union and other markets. This further illustrates potentially misleading nature of gross bilateral trade imbalances.²

²Figure F1 also shows that the Korea-China-U.S. triple trade relationship is similar to the Japan-China-U.S. one.

Figure F1: Gross and VA Balance of Trade, 2004

Note: The first country labeled in each pair is the surplus country while the second runs a deficit. Numbers in parentheses are the ratio of value-added to gross surplus.
